

Linear Programming

“program” as in “exercise program” or “spending program”, not “C program”

optimization problem with linear inequalities

variables $x_1 \dots x_d$ in d -dimensions.

$$\max \quad c_1 x_1 + c_2 x_2 + \dots + c_d x_d$$

$$\text{s.t.} \quad a_{11} x_1 + a_{12} x_2 + \dots + a_{1d} x_d \leq b_1$$

$$\vdots$$

$$a_{n1} x_1 + \dots + a_{nd} x_d \leq b_n$$

i.e.

$$\max \quad c x$$

$$A x \leq b$$

c $1 \times d$ vector

x $d \times 1$ vector

A $n \times d$ matrix

b $n \times 1$

An application: planning menus.

d foods	apple  1	broccoli  2	...	milk  d
each with cost	c_1	c_2	...	c_d
n nutrients	protein 1	vitamin D 2	...	n
each with daily requirement	b_1	b_2	...	b_n
a_{ij} — amount of nutrient i in food j				

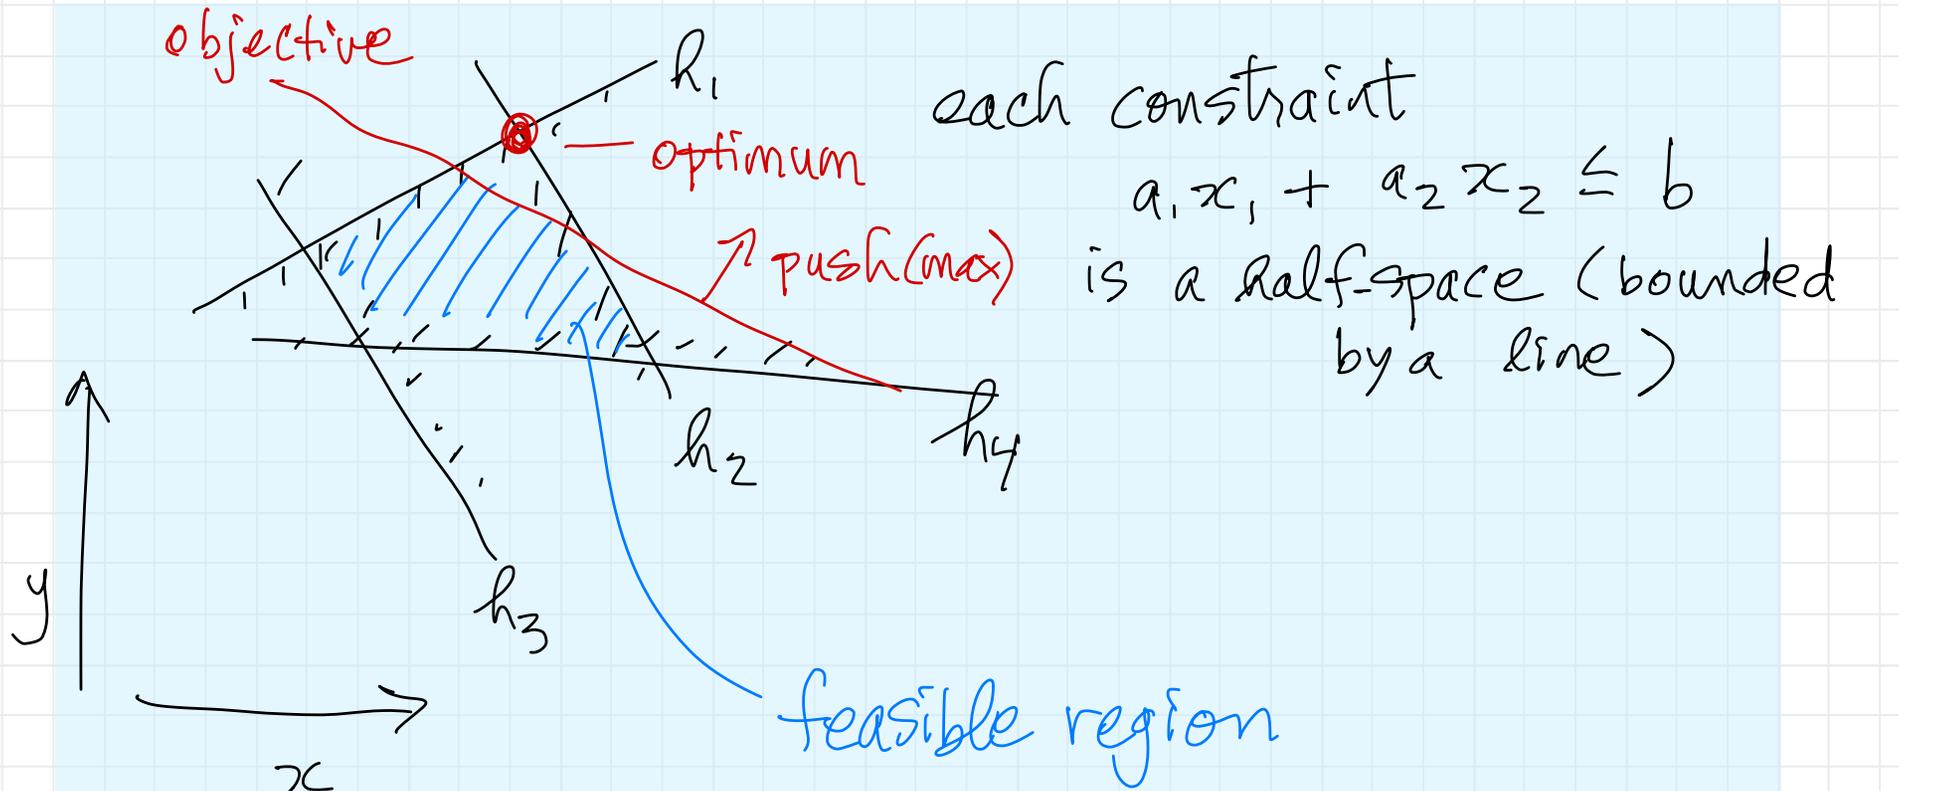

Buy food to
meet daily
requirements,
min cost

$$\min c x$$

$$A x \geq b$$

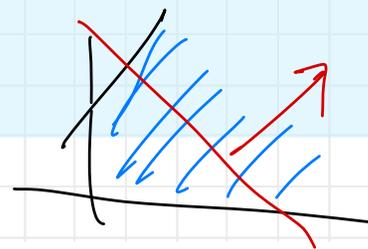

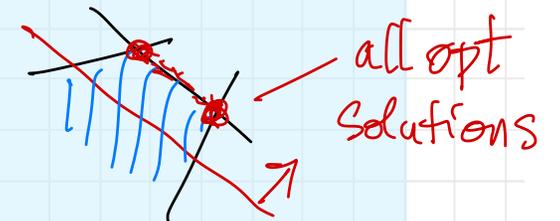

variables $x_1 \dots x_d$
 $x_j =$ amount of
food j to buy.

picture in 2D

Note: opt. soln need not be unique

May be unbounded

Straightforward algorithm:

try **all** vertices, see which gives max

previous

From ~~last day~~: this is the dual problem to Convex Hull and can be solved by same algorithms

$O(n \log n)$ in 2D, 3D

$O(n^{\lfloor d/2 \rfloor})$ for $d \geq 4$

But we don't really want all the vertices, so we can do better.

History

early 40's, 50's

George Dantzig

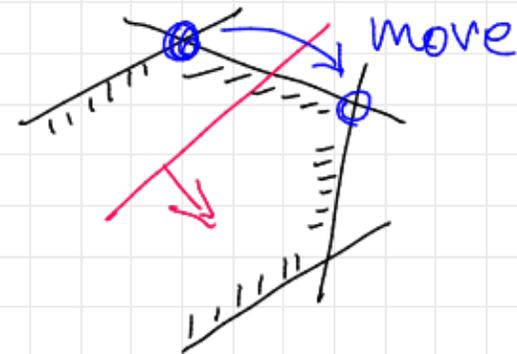

- simplex method in the '40's

https://en.wikipedia.org/wiki/George_Dantzig

Simplex Method

- geometrically — walk from one vertex of the feasible region to an adjacent one
- Simplex pivot rule
 - which inequality to remove
 - which one to add

a great intro to linear programming:

[Understanding and using linear programming.](#)

J Matousek, B Gärtner - 2007

History

OPEN: is there a pivot rule that gives a polynomial time algorithm?

But the simplex algorithm is very good in practice.

Related question:

Given initial vertex s and final vertex t (on a convex polyhedron),
how many edges on the shortest path from s to t ?

diameter of the polyhedron = worst case over all s and t

Hirsch conjecture.  https://en.wikipedia.org/wiki/Hirsch_conjecture

The diameter of a convex polyhedron is $\leq n - d$
where n = number of inequalities, d = dimension

disproved in 2012, $d = 43$.

But there could still be a polynomial (or even linear) bound.

back in '79 open NP-complete vs P
 - linear programming - in P
 - primality. - in P 2002
 - graph isomorphism - still open

History

Polynomial time algorithms for Linear Programming:

'80 — Khachiyan, ellipsoid method

'84 — Karmarkar, interior point method

front page NYT 1984

these operate on the bit representations of the numbers

OPEN: an LP algorithm that uses number of arithmetic operations polynomial in n and d , “strongly polynomial time”

“smoothed analysis” explains the good behaviour of the simplex method

https://en.wikipedia.org/wiki/Smoothed_analysis

The simplex algorithm is NP-mighty <https://doi.org/10.1145/3280847>

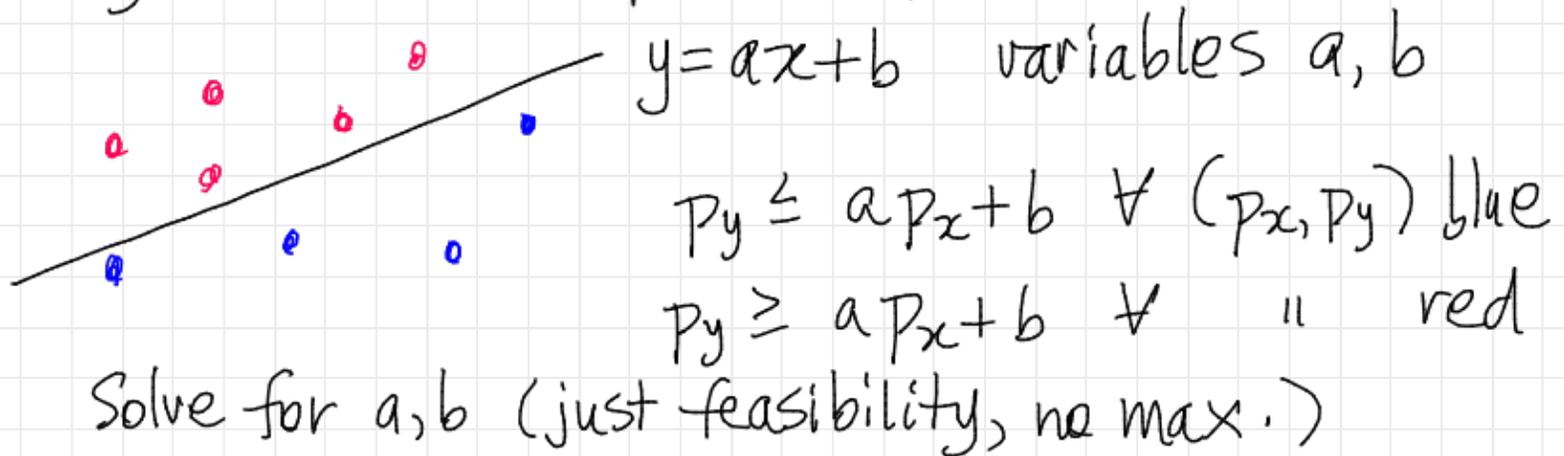

Y Disser, M Skutella - ACM Transactions on Algorithms (TALG), 2018 - dl.acm.org
 We show that the Simplex Method, the Network Simplex Method—both with Dantzig's original pivot rule—and the Successive Shortest Path Algorithm are NP-mighty. That is, each of these algorithms can be used to solve, with polynomial overhead, any problem in NP implicitly during the algorithm's execution. This result casts a more favorable light on these algorithms' exponential worst-case running times. Furthermore, as a consequence of our approach, we obtain several novel hardness results. For example, for a given input to the ...

Linear Programming in Small Dimensions

Applications

1. Separating red and blue points by a line

... and can check red below, blue above ... vertical line ..

Can also ask for strict separation

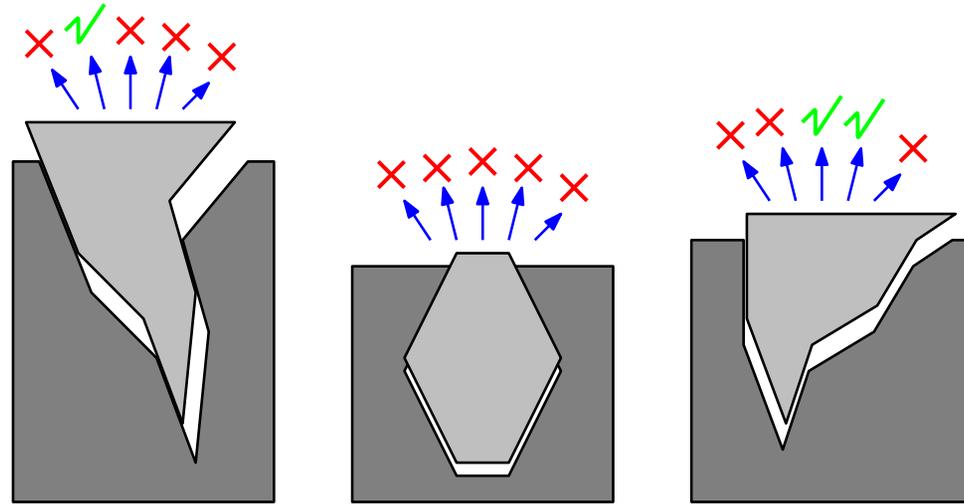

$$P_y < aP_x + b \quad \Rightarrow \quad P_y \leq aP_x + b + \delta$$

δ a variable, $\delta \geq 0$
maximize δ .

Linear programming in small (fixed) dimension d

Application: Casting (from [CGAA]). Make a 3D object in a mold

picture in 2D

Alper Ungor

Pour liquid into a mold, harden, and then remove by straight line motion in some direction. Find a direction that works.

For a given top face, this can be expressed as linear programming. — Ex. Try all top faces.

Linear programming in small (fixed) dimension

Megiddo 1984, algorithm with runtime $O(n)$

but the dependence on d is bad $O(2^{2^d} n)$

Seidel 1991, randomized algorithm with expected runtime $O(n)$

dependence on d $O(d! n)$

comparing 2^{2^d} vs $d!$

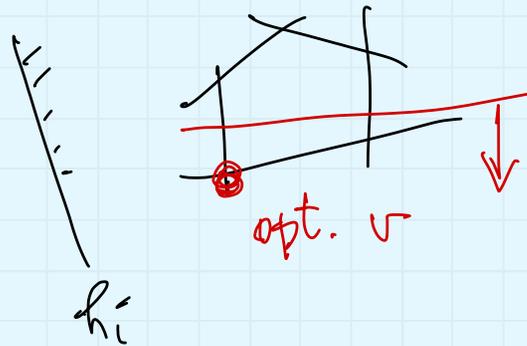

take logs 2^d vs $d \log d$

Randomized Incremental Algorithm in 2D, Seidel

Idea: add the halfplanes one by one in random order, updating the optimum solution vertex v each time

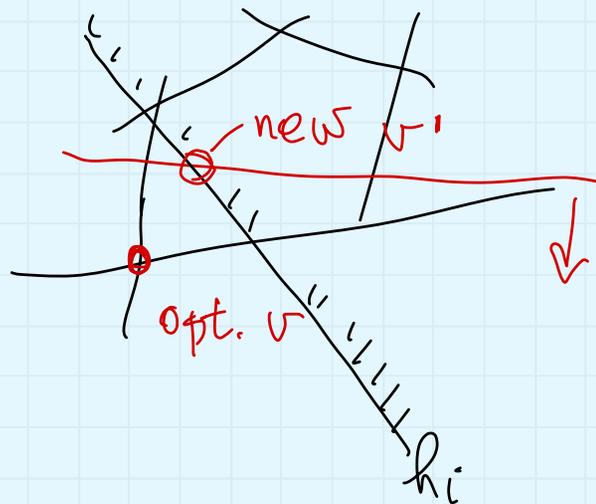

To add h_i . Two cases:

①

$v \in h_i$ — no update required

②

$v \notin h_i$ — we must update v

Claim. new opt will lie on line l_i of h_i

Solve 1-dimensional linear program (LP) on line l_i

We reduced to 1D Linear Programming.
What is 1D Linear Programming?

$$\begin{aligned} & \max x \\ & \text{subject to} \\ & \quad x \leq 2 \\ & \quad -1 \leq x \\ & \quad x \leq 5 \end{aligned}$$

Solution is easy $O(n)$ $n = \# \text{ constraints}$

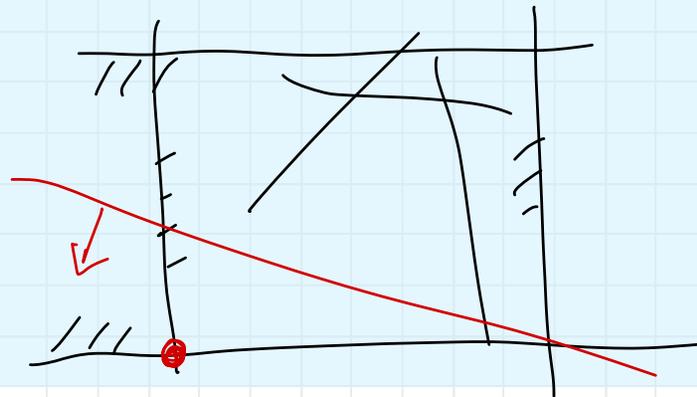

- max of lower bounds
- min of upper bounds.

Some issues:

What is the initial vertex (when there are no halfplanes)?

What if the LP is “unbounded”, (e.g. $\max x, x \geq 0$)

Soln Add a large box — containing all vertices.

$v \leftarrow$ opt. vertex of box.

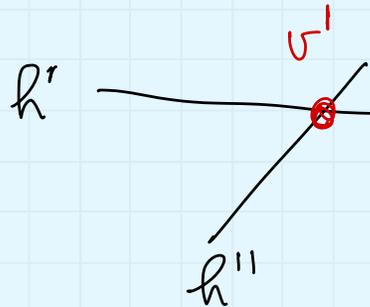

if final v on box
then original was
unbounded.

The method also needs the optimum to be unique — handle this by asking for optimum, then (to break ties) the lexicographically largest (i.e. $\max x_1$, then $\max x_2, \dots$)

Expected runtime

use backwards analysis

Suppose adding h_i causes work — we update to v^i

Then v^i is at intersection of two lines of halfplanes (else we would not update)

one of h' or h'' is h_i

We've processed from $1 \dots i$

* h_i is equally likely to any of them

We did update only if h_i is h' or h''

$$\text{Prob} \{ h_i = h' \text{ or } h_i = h'' \} = \frac{2}{i}$$

Expected total work of updates

$$\text{is } \sum_{i=1}^n \frac{2}{i} \cdot O(i) = O(n)$$

In higher dimensions

$\frac{2}{i}$ becomes $\frac{d}{i}$ because it takes d hyperplanes to specify a vertex

for expected runtime

run time recurrence: $T_d(n) = T_d(n-1) + \frac{d}{n} O(T_{d-1}(n))$

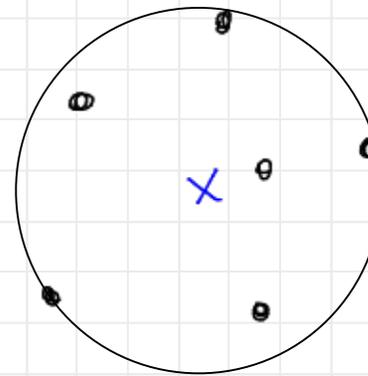

solution is: $T_d(n) = O(d! n)$ (prove by induction)

Smallest enclosing disc

Not a linear programming problem, but amenable to the same approach

Given points $p_1, \dots, p_n \in \mathbb{R}^d$

find the smallest enclosing sphere.

smallest enclosing
disc in 2D

This is a facility location problem — the center of the disc minimizes the maximum distance to all points.

Natural formulation gives quadratic programming.

Megiddo's approach gives $O(n)$ but bad constant.

Randomized incremental approach, Welzl, 1991.

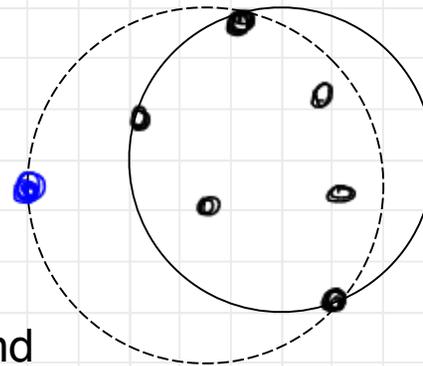

note that the smallest disc will go through 3 points

Smallest enclosing disc. Randomized incremental algorithm.
Suppose we have the solution for $n - 1$ points.

equation of circle

$$(x - c_x)^2 + (y - c_y)^2 = r^2$$

new point p

FACT: updated disc goes through p

New problem: min disc enclosing P and going through p

$W(P, R)$ — find smallest disc enclosing points P with points R on the boundary.
 $|R| \leq 3$. Initially P is the whole set of points and $R = \emptyset$

if $|R| = 3$ then circle unique

if $P = \emptyset$ easy

randomly choose one point

$D := W(P - \{p\}, R)$

if $p \in D$ return D

else return $W(P - \{p\}, R \cup \{p\})$

Expected run time $O(n)$ (no details)

Summary

- brief intro to linear programming
- linear programming in fixed dimension — randomized algorithm with expected run time $O(n)$
