Abstract

Language forms, their interpretations, and their linguistic families are introduced, analogously to grammar forms. These notions enable us to prove the following three results for grammar forms:

(i) the interval of all super-regular grammatical families is not maximally dense,

(ii) there is no maximally dense interval of grammatical families which contain the family of regular languages, and

(iii) it is decidable whether or not an interval of grammatical families containing the family of regular languages is dense.
1. Introduction

In [MSW2] the study of dense hierarchies or intervals of grammatical families generated by grammar forms has been initiated. We say that a pair of grammatical families \( (\mathcal{L}_1, \mathcal{L}_2) \) forms a dense interval if \( \mathcal{L}_1 \not\subseteq \mathcal{L}_2 \) and for every pair of grammatical families \( \mathcal{L}_3 \) and \( \mathcal{L}_4 \) satisfying \( \mathcal{L}_1 \subseteq \mathcal{L}_3 \not\subseteq \mathcal{L}_4 \subseteq \mathcal{L}_2 \) there exists a grammatical family properly in between \( \mathcal{L}_3 \) and \( \mathcal{L}_4 \).

Although the interval \( (\mathcal{L}(\text{REG}), \mathcal{L}(\text{CF})) \) is shown to be dense in [MSW2], the question of its maximality within the collection of context-free grammatical families was left open. This interval is maximal if for all grammatical families \( \mathcal{L} \not\subseteq \mathcal{L}(\text{REG}), (\mathcal{L}, \mathcal{L}(\text{CF})) \) is not dense.

In the present paper we resolve this issue by demonstrating that \( (\mathcal{L}(\text{REG}), \mathcal{L}(\text{CF})) \) is not maximal. To this end we introduce the general notion of a language form, which turns out to be crucial in the solution of this problem, enabling us to provide a characterization of those \( L_1 \) and \( L_2 \) for which \( (\mathcal{L}(L_1), \mathcal{L}(L_2)) \) is dense. Moreover we strengthen this result considerably by proving that there is no maximally dense interval \( (\mathcal{L}, \mathcal{L}(\text{CF})) \). Finally, we prove that it is decidable whether or not \( (\mathcal{L}, \mathcal{L}(\text{REG})) \) and, hence \( (\mathcal{L}, \mathcal{L}(\text{CF})) \) is a dense interval.

The paper consists of a further three sections. Section 2 provides the basic definitions and preliminary results. Although this paper is dependent on some earlier results, we
have attempted to make it as self-contained as possible. The crucial results of earlier papers are the four propositions stated in Section 2. Section 3 states and proves two Density Characterization Theorems, while Section 4 considers various implications of these Theorems.
2. Basic Notation and Results

In this section we not only introduce the basic notions and state some propositions, but we also prove some preliminary results.

Throughout this paper we use the following convention regarding homomorphisms.

Convention: Every homomorphism \( h: \Sigma^* \to \Delta^* \) is assumed to be a literal (letter-to-letter) homomorphism, that is \( h(\Sigma) \subseteq \Delta \). We use the terms homomorphism and morphism interchangeably.

Let \( L \) be a language, then by \( \text{alph}(L) \) we denote its alphabet. We say \( L \) is looping if either \( L \) contains a word containing two distinct appearances of the same letter or there exist distinct words \( w_1, \ldots, w_n \) in \( L \) and distinct letters \( a_1, \ldots, a_n \) in \( \text{alph}(L) \), for \( n \geq 2 \) such that \( a_i, a_{i+1} \) are in \( w_i \), \( 1 \leq i < n \) and \( a_n, a_1 \) are in \( w_n \). If \( L \) is not looping we say it is nonlooping.

Let \( L \subseteq \Sigma^* \) and \( L' \subseteq \Sigma'^* \) then \( L' \) is an interpretation of \( L \), denoted by \( L' \preceq L \), if there exists a morphism \( h: \Sigma'^* \to \Sigma^* \) such that \( h(L') \subseteq L \). We say \( L' \) is a regular interpretation, finite interpretation or nonlooping interpretation of \( L \) denoted by \( L' \preceq_r L \), \( L' \preceq_f L \) or \( L' \preceq_n L \), respectively, if \( L' \preceq L \) and \( L' \) is regular, finite or nonlooping, respectively. A language interpreted in this manner is also called a language form.
Each language $L$ defines a family of languages under interpretation, denoted by $L(L)$, $L_r(L)$, $L_f(L)$ or $L_n(L)$, we call these the *linguistical*, *r-linguistical*, etc., *families of $L$*. For example $L(L) = \{L' : L' \Rightarrow L\}$. Note that $L(L_1) \subseteq L(L_2)$ iff $L_1 \Rightarrow L_2$ and similarly for $r$, etc.

The importance of these various notions stems from the following result.

**Proposition 2.1 [MSW3]**

For all languages $L_1$ and $L_2$,

$$L(L_1) = L(L_2) \iff L_f(L_1) = L_f(L_2).$$

In other words a family is characterized completely by the finite languages it generates. Of course it follows immediately that $L_r(L_1) = L_r(L_2) \iff L_f(L_1) = L_f(L_2)$.

We now introduce the notion of interpretation for context-free grammars, in which case we call them *grammar forms*, for further details see [Wo]. A (context-free) grammar $G$ is a quadruple $G = (V, \Sigma, P, S)$ where $V$ is an alphabet, $P \subseteq (V - \Sigma)^*$ is a finite set of productions, usually written as $A \to \alpha$, and $S$ in $V - \Sigma$ is the sentence symbol. It is well known that we can associate a language with each grammar $G$, denoted by
L(G), where L(G) \subseteq \Sigma^*. For further details consult Harrison [H] or Hopcroft and Ullman [HU].

Let G_i = (V_i, \Sigma_i, P_i, S_i) be context-free grammars, where i = 1,2. Then G_1 is an interpretation of G_2, denoted by G_1 \triangleright G_2, if there exists a morphism h: V_1^* \rightarrow V_2^* such that:

\[\begin{align*}
h(V_1 - \Sigma_1) &\subseteq V_2 - \Sigma_2, \quad h(\Sigma_1) \subseteq \Sigma_2, \\
h(P_1) &\subseteq P_2 \text{ and } h(S_1) = S_2,
\end{align*}\]

where h(P_1) is defined as if P_1 is a finite language with words A \rightarrow \alpha, and h(\rightarrow) = \rightarrow_\ast.

With a grammar form G we associate its grammatical family \( \mathcal{L}(G) \), defined by \( \mathcal{L}(G) = \{L(G') : G' \triangleright G\} \).

A sub-regular grammar form G and its language L(G) are related in the form sense by the following proposition.

**Proposition 2.2** [OSW]

For all context-free grammars G such that \( \mathcal{L}(G) \) consists solely of regular languages

\[\mathcal{L}(G) = \mathcal{L}_r(L(G)).\]

Note that this result does not hold for "context-free interpretations" of languages.
We say that a language $L$ is minimal if there is no $L' \not\subseteq L$ such that $L(L') = L(L)$. Given $L_1$ and $L_2$ such that $L(L_1) = L(L_2)$ then $L_1$ is said to be equivalent to $L_2$, denoted by $L_1 \sim L_2$, otherwise $L_1$ is inequivalent to $L_2$, denoted by $L_1 \not\sim L_2$. If $L_1 \not\preceq L_2$ and $L_1 \not\prec L_2$ then we say $L_1$ is a proper interpretation of $L_2$, written $L_1 \prec L_2$. By $L_1 \not\prec L_2$ we denote that $L_1$ is not an interpretation of $L_2$.

Since we also discuss regular and nonlooping interpretations in the following we add a subscript to $\preceq$, $\prec$, $\preceq$, $\prec$, $\sim$ giving $\preceq_r$, $\prec_r$, $\sim_r$, for example.

The two central notions of this paper are captured by:

**Definition**

Let $L_1$ and $L_2$ be two grammatical families satisfying $L_1 \not\subseteq L_2$. Then $L_1 \preceq L_2$, denotes $L_1$ is a predecessor of $L_2$, if there is no grammatical family $L_3$ with $L_1 \not\subseteq L_3 \not\subseteq L_2$.

We say that $(L_1, L_2)$ forms a dense interval (of grammatical families) if for every pair of grammatical families $L_3$ and $L_4$ satisfying

$$L_1 \subseteq L_3 \not\subseteq L_4 \subseteq L_2$$
there is a grammatical family $\mathcal{L}_5$ with $\mathcal{L}_3 \not\in \mathcal{L}_5 \not\in \mathcal{L}_4$. In a similar manner we define these notions for linguistical families generated under the various interpretation mechanisms. Typically we will write $L_1 \text{ pred } L_2$ and $(L_1, L_2)$ rather than \(\mathcal{L}(L_1) \text{ pred } \mathcal{L}(L_2)\) and \((\mathcal{L}(L_1), \mathcal{L}(L_2))\), respectively, in this case and speak of \(r\)-denseness when we mean \((\mathcal{L}_r(L_1), \mathcal{L}_r(L_2))\) is dense with respect to $r$.

Note that Proposition 2.2 connects dense intervals of sub-regular grammatical families with \(r\)-dense intervals of the corresponding linguistical families.

It should be clear that an interval \((\mathcal{L}_1, \mathcal{L}_2)\) is dense (\(r\)-dense) if there is no $\mathcal{L}_3$ in the interval with a predecessor (\(r\)-predecessor) also in the interval. We characterize those language forms which have a predecessor in the following two theorems. However we need to define some preliminary notions first of all.

**Definition**

Let $L_1 \subseteq \Sigma_1^*$ and $L_2 \subseteq \Sigma_2^*$ be two languages. Then the super-disjoint union of $L_1$ and $L_2$, denoted by $L_1 \pitchfork L_2$, is defined as $L_1 \cup L_2$ if $\Sigma_1 \cap \Sigma_2 = \emptyset$ and is undefined otherwise. If $L_1$ and $L_2$ are language forms, we can always rename their alphabets to obtain disjointness, so in this case it is assumed that $L_1 \pitchfork L_2$ is always well-defined.
Let \( L \subseteq \Sigma^* \) be a language. We say that \( L \) is \textit{incoherent} if it can be decomposed into nontrivial \( L_1 \) and \( L_2 \) such that \( L_1 \cup L_2 = L \) (by nontrivial we mean \( L_1 \neq \emptyset \) and \( L_1 \neq \{\lambda\} \), where \( \lambda \) is the empty word). Otherwise we say \( L \) is \textit{coherent}.

In [MSW1] the following two results have been proved:

\begin{proposition}
Let \( L \) be a finite coherent language. Then \( L \) has a predecessor iff \( L \) is nonlooping.
\end{proposition}

\begin{proposition}
A minimal finite language \( L \) has a predecessor iff \( L = K \cup N \) for some \( K \) and \( N \), where \( N \) is nonlooping.
\end{proposition}

\begin{theorem}
Let \( L \) be a coherent language. Then \( L \) has a predecessor iff \( L \) is nonlooping.
\end{theorem}

\textbf{Proof:} If \( L \) is finite the result follows by Proposition 2.3. Hence consider infinite \( L \) only. Observe that every infinite \( L \) is looping, hence it only remains to show that such an \( L \) cannot have a predecessor. Therefore assume \( L \) has a predecessor \( P \). Now \( P \not\subset L \) and hence there exists a finite \( F \) with \( F \not\subset L \) but \( F \not\subset P \) by Proposition 2.1.
Consider \( P \supseteq F \). Clearly \( P \nsubseteq P \cup F \supseteq L \). Moreover \( L \nsubseteq P \cup F \) since \( L \nsubseteq P \) by assumption, \( L \nsubseteq F \), since \( L \) is infinite, and \( L \) is coherent. This contradicts the assumption that \( P \operatorname{pred} L \). Hence \( L \) has no predecessor. \( \square \)

We also have the general result.

**Theorem 2.6**

A minimal language \( L \) has a predecessor iff \( L = K \cup N \) for some \( K \) and \( N \), where \( N \) is nonlooping.

**Proof:** This is similar to the proof of Proposition 2.4 and is therefore omitted. \( \square \)

Finally we demonstrate that denseness implies \( r \)-denseness for regular linguistical families.

**Lemma 2.7**

Let \( L_1 \) and \( L_2 \) be two regular languages with \( L_1 \nsubseteq L_2 \). Then if \((L_1,L_2)\) is dense, \((L_1,L_2)\) is \( r \)-dense also.

**Proof:** Assume that \((L_1,L_2)\) is not \( r \)-dense. Then by the remarks above there exists \( L \) and \( P \) satisfying \( L_1 \nsubseteq P \nsubseteq L \nsubseteq L_2 \) and \( P \operatorname{pred} L \). Now \( P \nsubseteq L \) implies \( P \nsubseteq L \) and since \((L_1,L_2)\) is dense, there exists \( Q \) with \( P \nsubseteq Q \nsubseteq L \). Now by Proposition...
2.1 there exists a finite $F_Q \not\vDash Q$ with $F_Q \not\vDash P$ and also there exists a finite $F_L$ with $F_L \not\vDash L$ and $F_L \not\vDash Q$. Putting these two facts together consider $P \cup F_Q$. Clearly $P \not\vDash P \cup F_Q \not\vDash L$, since $P \cup F_Q$ is regular. This is a contradiction, hence $(L_1, L_2)$ is $r$-dense.
3. **The Density Characterization Theorems**

One of the major obstacles to proving decidability results for intervals of grammatical families has been the lack of a density characterization theorem for such intervals. In the present section we provide such theorems which are then used to provide examples of dense intervals.

**Theorem 3.1: The First Density Characterization Theorem**

Given two languages $L_1$ and $L_2$ with $L_1 \nsubseteq L_2$, then $(L_1, L_2)$ is dense if and only if $L_1 \nsubseteq L_2$.

Similarly, if $L_1 \nsubseteq r L_2$, then $(L_1, L_2)$ is $r$-dense if and only if $L_1 \nsubseteq L_2$.

**Proof:** The second statement follows from the first by way of Lemma 2.7, hence we will only prove the first statement here.

Without loss of generality assume both $L_1$ and $L_2$ are minimal.

**if:** Assume $L_1 \nsubseteq L_2$. Observe that for all $L$,

$$L_1 \nsubseteq L \nsubseteq L_2, \quad L \nsubseteq L_1.$$
Let $L_2 = L'_2 \cup M_1 \cup \ldots \cup M_m$, for coherent nonlooping $M_i$, $1 \leq i \leq m$ and $L'_2$ looping, where $L'_2$ cannot be further decomposed under $\cup$ into a non-empty nonlooping language and a looping language. We say the above decomposition of $L_2$ is the maximal non-looping decomposition for $L_2$. Similarly, let $L_1 = L'_1 \cup K_1 \cup \ldots \cup K_k$ be the maximal nonlooping decomposition for $L_1$.

Since $L_1 \not\leq L_2$, $M_i \not\leq L'_1$, $1 \leq i \leq m$. Furthermore each $M_i \not\leq L'_1$ since this would contradict the minimality of $L_2$. Therefore $M_i \not\leq K_j$ for some $j$. Similarly $K_j \not\leq M_i$, otherwise it would contradict the minimality of $L_1$. Hence $M_i \sim K_j$.

This implies we can write $L_1$ as $L'_1 \cup M_1 \cup \ldots \cup M_m \cup N_1 \cup \ldots \cup N_n$, where $n \geq 0$ and the $N_i$ are coherent and nonlooping.

Note that $L'_2 \not= \emptyset$. Otherwise $L_1 \not\leq L_2$ implies $L'_1 = \emptyset$, since a looping language cannot be obtained from a nonlooping one. Moreover in this case $n = 0$ and hence $L_1 \sim L_2$, a contradiction.

Finally consider minimal $L_3$ and $L_4$ such that

$L_1 \not\leq L_3 \leq L_4 \not\leq L_2$.

Then by similar arguments to those for $L_1$ above we can express $L_3$ as

$L'_3 \cup M_1 \cup \ldots \cup M_m \cup N_1 \cup \ldots \cup N_s$
and

\[ L_4 \preceq L'_4 \preceq M_1 \preceq \ldots \preceq M_m \preceq N_1 \preceq \ldots \preceq N_k, \]

where

\[ 1 \leq t \leq s \leq n. \]

Moreover, \( L'_3 \) can be expressed as \( J_1 \preceq \ldots \preceq J_p \) and \( L'_4 \) as \( K_1 \preceq \ldots \preceq K_q \), where each of the \( J_i \) and \( K_i \) are looping and coherent. We now show that we can always construct an \( L \) such that \( L'_3 \npreceq L \npreceq L'_4 \).

(i) \( s = t \). In this case there exists an \( i \) such that for all \( j, 1 \leq j \leq p \) either \( J_j \npreceq K_i \) or \( J_j \npreceq K_i \). For otherwise \( L'_3 \sim L'_4 \) and hence \( L'_3 \sim L_4 \). Since \( K_i \) is looping it has no predecessor (by Theorem 2.5). Therefore consider a \( K'_i \npreceq K_i \) which also satisfies \( K'_i \npreceq J_j, 1 \leq j \leq p \). Such a \( K'_i \) must exist since there are only finitely many \( J_j \npreceq K_i \). To conclude this subcase observe that \( L'_3 \npreceq K'_i \) is properly between \( L'_3 \) and \( L'_4 \).
(ii) $s \rightarrow t$. Now $N_{t+1} \cup \ldots \cup N_z \preceq K_1 \cup \ldots \cup K_q$, otherwise we would have a contradiction to the minimality of $L_3$. In particular this implies $N_{t+1} \preceq K_i$ for some $i$, $1 \leq i \leq q$. Consider $K'_i$ such that $N_{t+1} \nless K'_i \preceq k_i$. Surely such a $K'_i$ exists and furthermore as in subcase (i) $L_3 \not\preceq L_3 \cup K'_i \not\preceq L_4$.

**only if:** Assume $(L_1, L_2)$ is dense. Now if $L_1 \not\preceq L_2$, then there exists a coherent nonlooping $F \preceq L_2$ such that $F \not\preceq L_1$. But this implies $L_1 \not\preceq L_1 \cup F \preceq L_2$ and by Theorem 2.6 $L_1 \cup P$ is a predecessor of $L_1 \cup F$, if $P$ is the predecessor of $F$. But this implies $(L_1, L_2)$ is not dense, a contradiction. □

**Corollary 3.2**

For an arbitrary regular language $L$, $(L_r(L), L(REG))$ is $r$-dense iff $L$ is $n$-complete and $L_r(L) \not\preceq L(REG)$.

**Corollary 3.3**

For two arbitrary $L_1$ and $L_2$ with $L_1 \preceq L_2$, $(L_1, L_2)$ is not $r$-dense if $L_1$ is nonlooping.

This follows by observing that if $L_2$ is nonlooping then $L_2 \preceq L_1$ and hence $L_1 \not\preceq L_2$. On the other hand if $L_2$ is
looping then it can generate arbitrarily long chains of words (or broken loops, see [MSW1]) and \( L_1 \) cannot, hence once again \( L_1 \not\subset L_2 \).

**Corollary 3.4**

The interval \((\mathcal{L}_r(L), \mathcal{L}(\text{REG}))\) is not \( r \)-dense, where \( L = (a^* - \{a^2\}) \cup \{ab, ba, b\} \).

**Proof:** Consider the language \( M = \{ab, acd, bef\} \). Clearly \( M \) is nonlooping and \( M \) is minimal and coherent. Now both \( a \) and \( b \) appear in a word of length 3. Therefore letting \( h \) be a morphism such that \( h(M) \subseteq L \), it follows that \( h(acd) = h(bef) = aaa \) and hence \( h(ab) = aa \). But \( aa \) is not in \( L \), hence \( M \not\subset L \) and by Corollary 3.2 \((L, a^*)\) is not dense. \( \square \)

To enable us to present specific \( r \)-dense intervals of the form \((\mathcal{L}, \mathcal{L}(\text{REG}))\) we need to strengthen Theorem 3.1 for the case of \( n \)-completeness. This we now do by way of the following definitions.

Let \( L \subseteq \Sigma^* \) be an arbitrary nonlooping language and let \( L' = L - \Sigma \). We say a word \( w \) in \( L' \) is **isolated** if \( \text{alph}(w) \cap \text{alph}(L' - \{w\}) = \emptyset \). We say a word \( w \) in \( L \) is an **end word** if
\[ \alpha(w) \cap \alpha(L' - \{ w \}) = \{ a \}, \text{ for some } a \in \Sigma. \]

In this case we say \( w \) connects \( w \) and \( L' - \{ w \} \). We say a word \( w \) in \( L \) is an inner word if it is neither an isolated word nor an end word.

**Lemma 3.5**

Every coherent nontrivial nonlooping language \( N \) has at least one end word if \( \#N \geq 2 \).

**Proof:** Immediate.

We are now ready to state and prove our second characterization theorem.

**Theorem 3.6:** The Second Density Characterization Theorem

Let \( L \) be an arbitrary language.

Then \( (L, a^*) \) is \( r \)-dense iff \( L \) has a subset \( L' \) for which the following condition obtains:

For all letters \( a \) in \( \alpha(L') \) and for all \( i, j \geq 0 \) there is a word \( x \) in \( \alpha(L') \)^\( i \) and a word \( y \) in \( \alpha(L') \)^\( j \) such that \( xay \) is in \( L' \).

In other words \( L \) is \( n \)-complete iff it has such a subset \( L' \).
Proof: In this proof whenever an n-complete language is mentioned we always assume it is also minimal, that is every proper subset of it is not n-complete. Clearly this is no loss of generality since each n-complete language has a minimal n-complete subset.

Because of Theorem 3.2 we only need consider the case that L is n-complete, since a* is obviously n-complete.

if: To show that L is n-complete we need to prove that every nonlooping language N has a morphic image in L' and hence in L. We prove this by induction on the cardinality of N. Note that L' contains words of all lengths. For #N = 1, since the only word must consist of distinct letters it trivially has a morphic image in L'.

Now assume that for some k ≥ 1, every N with #N ≤ k, has a morphic image which is a subset of L'.

Let N be a nonlooping language with #N = k + 1. For w an end word in N there is a morphism h such that h(N-{w}) is a subset of L'.

Consider the connecting symbol a in w. Then we can write w as b_1 ... b_i a b_{i+1} ... b_n, where 0 ≤ i ≤ n. Clearly there is a word v in L' satisfying
\[ v = x_1 h(a) x_2, \]

where \( |x_1| = i \) and \( |x_2| = n - i \).

Note that the letters \( b_1, \ldots, b_n \) are distinct from each other and from \( \text{alph}(N - \{w\}) \). Hence we can extend \( h \) to these new symbols such that \( h(w) = v \). In other words \( h(N) \subseteq L' \) completing this part of the proof.

**only if:** \( L \) is minimal \( n \)-complete by assumption, hence we prove it satisfies the property in the Theorem statement.

Let \( a \) be a letter in \( \text{alph}(L) \) and let \( xay \) be a word in \( L \). Clearly there must be at least one such word with \( |xy| \neq 0 \) otherwise \( L \) would not be minimal \( n \)-complete.

Now there is a nonlooping language \( N \) such that whenever \( h(N) \subseteq L \), then there is a word \( w \) in \( N \) with \( h(w) = xay \). If this is not the case \( L - \{xay\} \) is also \( n \)-complete, a contradiction of the minimality of \( L \). We define nonlooping languages \( M_{ij} \) for all \( i, j \geq 0 \) by:

For every symbol \( s \) in \( \text{alph}(N) \) add a word

\[ a_1 \ldots a_i sb_1 \ldots b_j \]

to \( N \), where \( a_2 \) and \( b_m \) are new symbols for every symbol \( s \) in \( \text{alph}(N) \).
Now since each $M_{ij}$ is nonlooping $M_{ij} \preceq L$ for all $i, j \geq 0$. Moreover whenever $g(M_{ij}) \subseteq L$, for some morphism $g$, then $g(w) = xay$ by the above remarks. Moreover $g(a_1 \ldots a_isb_1 \ldots b_j) = x_1ay_1$ in $L$, for some $s$ in alph($N$) and hence $L$ satisfies the property in the Theorem statement, completing the proof. 

This leads immediately to some specific examples of $n$-complete languages and hence dense intervals.

**Corollary 3.7**

$L_1 = \{a,b\}^* - \{a^i,b^i : i \geq 2\}$ is $n$-complete and hence $(L_1, a^*)$ is an $r$-dense interval.

**Proof:** $L_1$ clearly satisfies the condition of Theorem 3.6.

**Corollary 3.8**

$L_2 = \{a,b,c\}^* - \{a^3,b^3,c^3,aab,aac,aba,aca,baa,caa,bbc,bcb,cbb\}$ is $n$-complete.

More importantly:

**Corollary 3.9**

Let $\Sigma_m = \{a_1,a_2,\ldots,a_m\}$ and $K_m = \{\Sigma^* - \Sigma^2\} \cup \{a_1a_2a_3,\ldots,a_ma_1\}$. Then $K_m$ is $n$-complete.
4. **Decidability and Maximaliy**

In this section we first prove that $n$-completeness is decidable for context-free languages, and then go on to show not only is $(\mathcal{L}(\text{REG}), \mathcal{L}(\text{CF}))$ not a maximally dense interval, but also there is no maximally $r$-dense interval $(L, a^*)$.

**Theorem 4.1**

$N$-completeness is decidable for context-free languages.

**Proof:** $L$ is $n$-complete iff it has a subset $L'$, which satisfies the condition of Theorem 3.6, that is $L' = L \cap \Sigma^*$ for some $\Sigma \subseteq \text{alph}(L)$. Now define finite substitutions $\delta_a$ for all $a$ in $\Sigma$ by:

\[
\delta_a(a) = \{f, a\}
\]
\[
\delta_a(b) = \{f\}, \text{ for all } b \text{ in } \Sigma, \ b \neq a,
\]

where $f$ is a new symbol.

Clearly $L'$ satisfies the condition of Theorem 3.6 iff $M_a = \delta_a(L') \cap f^*af^* = f^*af^*$, for all $a$ in $\Sigma$.

This is decidable since $f^*af^*$ is a bounded regular set and $M_a$ is context-free. $\square$
In order to prove the maximality result we need to consider directed cycles of length \( m \), denoted by \( C_m \). Letting \( \Sigma_m = \{a_1, a_2, \ldots, a_m\} \) we define \( C_m \) by:

\[
C_m = \{a_1a_2a_3, \ldots, a_m a_1\}.
\]

It is a straightforward observation that

\[
C_r \triangleleft C_m \iff r = 0 \pmod{m}.
\]

On the other hand every nonlooping language \( N \subseteq \Sigma^2 \) is an interpretation of \( C_m \) for all \( m \geq 1 \).

We now have:

**Lemma 4.2**

Let \( L \) be an \( n \)-complete language.

Then there is an \( m \) such that \( C_m \subseteq L \).

**Proof:** We only need consider \( L' = \{w \text{ is in } L : |w| = 2\} \).

Let \( \#L' = r \). Now since all nonlooping languages are interpretations of \( L \), then in particular

\[
P_r = \{a_1a_2a_3, \ldots, a_ra_{r+1}a_{r+1}a_{r+2}\}
\]

is an interpretation of \( L' \), that is there is a morphism \( h \) such that \( h(P_r) \subseteq L' \).
Now $h$ cannot be one-to-one, since $\#P = r+1 > \#L'$. Therefore $h$ merges at least two letters and hence there is an $m \geq 1$ such that $C_m \subseteq h(P_r)$. But this implies $C_m \subseteq L' \subseteq L$, completing the proof.

We also need:

**Lemma 4.3**

Let $L_1$ and $L_2$ be regular languages. Then there is a regular language $L$ such that

$$\mathcal{L}(L) = \mathcal{L}(L_1) \cap \mathcal{L}(L_2)$$

and

$$\mathcal{L}_r(L) = \mathcal{L}_r(L_1) \cap \mathcal{L}_r(L_2).$$

**Proof:** This follows along the lines of the proof of Theorem 4.2 in [MSW4] and hence is left to the reader.

We are now able to prove our final result:

**Theorem 4.4**

There is no (regular) language $L$ such that $(L, a^*)$ is maximally dense ($r$-dense).
Proof: We show that every dense interval \((L, a^*)\) can be extended. In other words that there exists an \(L_0\) such that \(L_0 \ntriangleright L\) and \((L_0, a^*)\) is dense.

From Lemma 4.2 we know that there is an integer \(m \geq 1\) such that \(C_m \leq L\). Let \(m_0\) be the greatest such \(m\).

Immediately \(L' = \{w \text{ is in } L : |w| = 2\}\) is not an interpretation of \(C_{m_0+1}\), since \(C_{m_0} \nrightarrow C_{m_0+1}\).

Letting \(K_{m_0+1} = (\text{alph}(L)^* - \text{alph}(L)^2) \cup \{a_1a_2, \ldots, a_{m_0+1a}\}\).

Then \(C_{m_0+1} \leq K_{m_0+1}\) and moreover \(L\) is not an interpretation of \(K_{m_0+1}\). Now let \(L_0\) be a language such that

\[ L(L_0) = L(L) \cap L(K_{m_0+1}). \]

Note that \(L_0 \ntriangleright L\), since \(L\) is not in \(L(L_0)\).

It remains to demonstrate that \(L_0\) is n-complete. However \(L\) is n-complete by assumption and \(K_{m_0+1}\) is n-complete by Corollary 3.9. Hence \(L_0\) is n-complete and \((L_0, a^*)\) is both dense and an extension of \((L, a^*)\) as required. \(\square\)

Corollary 4.5

For all context-free grammar forms \(G\) with \(L(G), L(CF)\), the interval \((L(G), L(CF))\) is not maximally dense.

Thus a problem posed in [MSW2] has finally been solved.
