Computer Algebra in Scientific Computing  
Satisfiability Checking + Symbolic Computation (SC<sup>2</sup>) Track

# Motivation

*The research areas of SMT [SAT Modulo Theories] solving and symbolic computation are quite disconnected. On the one hand, SMT solving has its strength in efficient techniques for exploring Boolean structures, learning, combining solving techniques, and developing dedicated heuristics, but its current focus lies on easier theories and it makes use of symbolic computation results only in a rather naive way.*

# The MATHCHECK2 System

- ▶ Uses SAT and CAS functionality to finitely verify or counterexample conjectures in mathematics.
- ▶ Used to study conjectures in combinatorial design theory about the existence of Hadamard and Williamson matrices.

# Experimental Results

MATHECHECK2 was able to show that...

- ▶ Williamson matrices of order 35 do not exist.
  - ▶ First shown by Đoković<sup>2</sup>, who requested an independent verification.
- ▶ Williamson matrices exist for all orders  $n < 35$ .
  - ▶ Even orders were mostly previously unstudied.
- ▶ Found over 160 Hadamard matrices which were not previously in the library of the CAS MAGMA.
  - ▶ Orders up to  $168 \times 168$ .

---

<sup>2</sup>Williamson matrices of order  $4n$  for  $n = 33, 35, 39$ . *Discrete Mathematics*.

# Hadamard matrices

- ▶ square matrix with  $\pm 1$  entries
- ▶ any two distinct rows are orthogonal

# Hadamard matrices

- ▶ square matrix with  $\pm 1$  entries
- ▶ any two distinct rows are orthogonal

## Example

$$H = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ -1 & 1 & 1 & -1 \end{bmatrix}$$

## Conjecture

An  $n \times n$  Hadamard matrix exists for any  $n$  a multiple of 4.

## Naive Hadamard Encoding

Each entry of  $H$  will be represented using a *Boolean variable* encoding with  $BV(1) = \text{true}$  and  $BV(-1) = \text{false}$ .

Multiplication becomes XNOR under this encoding, i.e.,

$$BV(x \cdot y) = \neg(BV(x) \oplus BV(y)) \quad \text{for } x, y \in \{\pm 1\}.$$

# Naive Hadamard Encoding

## Arithmetic formula encoding

$$\sum_{k=0}^{n-1} h_{ik} \cdot h_{jk} = 0 \quad \text{for all } i \neq j.$$

## Boolean variable encoding

Using ‘product’ variables  $p_{ijk} := \text{BV}(h_{ik} \cdot h_{jk})$  this becomes the cardinality constraints

$$\sum_{\substack{k=0 \\ p_{ijk} \text{ true}}}^{n-1} 1 = \frac{n}{2} \quad \text{for all } i \neq j.$$

## Naive Hadamard Encoding

A *binary adder* consumes Boolean values and produces Boolean values; when thought of as bits, the outputs contain the binary representation of how many inputs were true.

To encode the cardinality constraints we use a network of binary adders with:

- ▶  $n$  inputs (the variables  $\{p_{ijk}\}_{k=0}^{n-1}$ )
- ▶  $\lfloor \log_2 n \rfloor + 1$  outputs (counting the number of input variables which are true)

# Williamson Matrices

- ▶  $n \times n$  matrices  $A, B, C, D$
- ▶ entries  $\pm 1$
- ▶ symmetric, circulant
- ▶  $A^2 + B^2 + C^2 + D^2 = 4nI_n$

# Symmetric and Circulant Matrices

Such matrices are defined by their first  $\lceil \frac{n+1}{2} \rceil$  entries so we may refer to them as if they were sequences.

Examples ( $n = 5$  and  $6$ )

$$\begin{bmatrix} a_0 & a_1 & a_2 & a_2 & a_1 \\ a_1 & a_0 & a_1 & a_2 & a_2 \\ a_2 & a_1 & a_0 & a_1 & a_2 \\ a_2 & a_2 & a_1 & a_0 & a_1 \\ a_1 & a_2 & a_2 & a_1 & a_0 \end{bmatrix}$$

symmetric conditions

$$\begin{bmatrix} a_0 & a_1 & a_2 & a_3 & a_2 & a_1 \\ a_1 & a_0 & a_1 & a_2 & a_3 & a_2 \\ a_2 & a_1 & a_0 & a_1 & a_2 & a_3 \\ a_3 & a_2 & a_1 & a_0 & a_1 & a_2 \\ a_2 & a_3 & a_2 & a_1 & a_0 & a_1 \\ a_1 & a_2 & a_3 & a_2 & a_1 & a_0 \end{bmatrix}$$

circulant conditions

# Symmetric and Circulant Matrices

Such matrices are defined by **their first  $\lceil \frac{n+1}{2} \rceil$  entries** so we may refer to them as if they were sequences.

Examples ( $n = 5$  and  $6$ )

$$\begin{bmatrix} a_0 & a_1 & a_2 & a_2 & a_1 \\ a_1 & a_0 & a_1 & a_2 & a_2 \\ a_2 & a_1 & a_0 & a_1 & a_2 \\ a_2 & a_2 & a_1 & a_0 & a_1 \\ a_1 & a_2 & a_2 & a_1 & a_0 \end{bmatrix}$$

symmetric conditions

$$\begin{bmatrix} a_0 & a_1 & a_2 & a_3 & a_2 & a_1 \\ a_1 & a_0 & a_1 & a_2 & a_3 & a_2 \\ a_2 & a_1 & a_0 & a_1 & a_2 & a_3 \\ a_3 & a_2 & a_1 & a_0 & a_1 & a_2 \\ a_2 & a_3 & a_2 & a_1 & a_0 & a_1 \\ a_1 & a_2 & a_3 & a_2 & a_1 & a_0 \end{bmatrix}$$

circulant conditions

# Williamson Matrices Sequences

- ▶ sequences  $A, B, C, D$  of length  $\lceil \frac{n+1}{2} \rceil$
- ▶ entries  $\pm 1$
- ▶  $\text{PAF}_A(s) + \text{PAF}_B(s) + \text{PAF}_C(s) + \text{PAF}_D(s) = 0$  for  $s = 1, \dots, \lceil \frac{n-1}{2} \rceil$ .

The  $\text{PAF}^3$  here is defined

$$\text{PAF}_A(s) := \sum_{k=0}^{n-1} a_k a_{(k+s) \bmod n}.$$

---

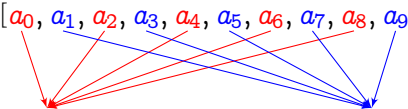

<sup>3</sup>Periodic Autocorrelation Function

# Compression

The  $m$ -compression of a sequence  $A = [a_0, \dots, a_{n-1}]$  of length  $n = dm$  is a new sequence of length  $d$  whose  $j$ th entry is the sum of  $a_{j+kd}$  for  $k = 0, \dots, m-1$ .

## Example

The sequence  $A = [a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9]$  has the 5-compression

$$A^{(2)} = [a_0 + a_2 + a_4 + a_6 + a_8, a_1 + a_3 + a_5 + a_7 + a_9].$$

# Compression

The  $m$ -compression of a sequence  $A = [a_0, \dots, a_{n-1}]$  of length  $n = dm$  is a new sequence of length  $d$  whose  $j$ th entry is the sum of  $a_{j+kd}$  for  $k = 0, \dots, m-1$ .

## Example

The sequence  $A = [a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9]$  has the 2-compression

$A^{(5)} = [a_0 + a_5, a_1 + a_6, a_2 + a_7, a_3 + a_8, a_4 + a_9].$

# Useful Properties of Compressed Sequences

## Lemma 1

The entries of an  $m$ -compression of a  $\pm 1$ -sequence of length  $dm$ :

- ▶ have absolute value at most  $m$
- ▶ have the same parity as  $m$

## Lemma 2

The compression of a symmetric sequence is also symmetric.

# Technique 1: Sum-of-squares Decomposition

Doković–Kotsireas<sup>4</sup> theorem

Williamson sequences satisfy

$$\text{PAF}_A(0) + \text{PAF}_B(0) + \text{PAF}_C(0) + \text{PAF}_D(0) = 4n$$

and this **still holds** even if  $A$ ,  $B$ ,  $C$ ,  $D$  are compressed.

With maximal compression, this becomes

$$\text{rowsum}(A)^2 + \text{rowsum}(B)^2 + \text{rowsum}(C)^2 + \text{rowsum}(D)^2 = 4n.$$

---

<sup>4</sup>Compression of periodic complementary sequences and applications.  
*Designs, Codes and Cryptography*

## Technique 1: Sum-of-squares Decomposition

Why is this useful?

CAS functionality can determine all possible solutions of

$$w^2 + x^2 + y^2 + z^2 = 4n \quad w, x, y, z \equiv n \pmod{2}.$$

This tells us all possible rowsums for Williamson sequences.

# Technique 1: Sum-of-squares Decomposition

Why is this useful?

CAS functionality can determine all possible solutions of

$$w^2 + x^2 + y^2 + z^2 = 4n \quad w, x, y, z \equiv n \pmod{2}.$$

This tells us all possible rowsums for Williamson sequences.

We can encode this information as constraints and pass it to the SAT solver.

# Technique 1: Sum-of-squares Decomposition

## Example

When  $n = 35$ , there are exactly three ways to write  $4n$  as a sum of four positive odd squares in ascending order:

$$1^2 + 3^2 + 3^2 + 11^2 = 4 \cdot 35$$

$$1^2 + 3^2 + 7^2 + 9^2 = 4 \cdot 35$$

$$3^2 + 5^2 + 5^2 + 9^2 = 4 \cdot 35$$

## Williamson Equivalences

Williamson sequences  $A, B, C, D$  can be re-ordered and negated without affecting the Williamson conditions.

Given this, we may enforce the constraint

$$0 \leq \text{rowsum}(A) \leq \text{rowsum}(B) \leq \text{rowsum}(C) \leq \text{rowsum}(D).$$

## Technique 2: Divide-and-conquer

For efficiency reasons, we want to partition the search space into subspaces. An effective way to do this is to have each subspace contain one possibility for the compressions of  $A$ ,  $B$ ,  $C$ ,  $D$ .

- ▶ Determine all possible compressions with Lemmas 1 and 2.
- ▶ Use the  $\text{DK}$  theorem to remove possibilities which are necessarily invalid (for example, because their *power spectral density* is too large).

## Power Spectral Density

The *power spectral density* of a sequence  $A$  is

$$\text{PSD}_A(s) := |\text{DFT}_A(s)|^2$$

where  $\text{DFT}_A$  is the *discrete Fourier transform* of  $A$ .

### Example

The power spectral density of  $A = [1, 1, -1, -1, 1]$  is given by:

$$\begin{aligned}\text{PSD}_A(0) &= 1^2 &&= 1 \\ \text{PSD}_A(1) &\approx 3.236^2 &&= 10.472 \\ \text{PSD}_A(2) &\approx (-1.236)^2 &&= 1.528 \\ \text{PSD}_A(3) &\approx (-1.236)^2 &&= 1.528 \\ \text{PSD}_A(4) &\approx 3.236^2 &&= 10.472\end{aligned}$$

## Đoković–Kotsireas Theorem

For all  $s \in \mathbb{Z}$ , Williamson sequences satisfy

$$\text{PSD}_A(s) + \text{PSD}_B(s) + \text{PSD}_C(s) + \text{PSD}_D(s) = 4n$$

and these **still hold** if  $A, B, C, D$  are compressed.

### Corollary

If  $\text{PSD}_X(s) > 4n$  then  $X$  is not a Williamson sequence or the compression of a Williamson sequence.

## Technique 2: Divide-and-conquer

For  $n = 35$  with 7-compression, the following is one of 119 compressions which satisfy the DK conditions:

$$A^{(5)} = [ 5, 1, -3, -3, 1 ]$$

$$B^{(5)} = [-3, 3, -3, -3, 3]$$

$$C^{(5)} = [-3, 1, -1, -1, 1]$$

$$D^{(5)} = [ 1, -3, -3, -3, -3 ]$$

## Technique 2: Divide-and-conquer

If  $n$  has more than one nontrivial factor it is possible to perform compression by both factors.

### Example

Using 5 and 7-compression on  $n = 35$  lead to the following number of instances for each decomposition type:

Instance type	# instances
$1^2 + 3^2 + 3^2 + 11^2$	6960
$1^2 + 3^2 + 7^2 + 9^2$	8424
$3^2 + 5^2 + 5^2 + 9^2$	6290

## Technique 3: UNSAT Core

The instances generated are very similar and a short reason why one instance is unsatisfiable may apply to other instances.

### Example

The  $n = 35$  instances contained 3376 variables but only 168 were set differently between instances.

## Experimental Results

Timings<sup>5</sup> for Williamson orders  $25 \leq n \leq 35$  are below. The number of SAT calls which successfully returned a result is in parenthesis. A hyphen denotes a timeout after 24h.

Order	Base	Sum-of-squares	Divide-and-conquer	UNSAT Core
25	317s (1)	1702s (4)	408s (179)	408s (179)
26	865s (1)	3818s (3)	61s (3136)	34s (1592)
27	5340s (1)	8593s (3)	1518s (14994)	1439s (689)
28	7674s (1)	2104s (2)	234s (13360)	158s (439)
29	-	21304s (1)	N/A	N/A
30	1684s (1)	36804s (1)	139s (370)	139s (370)
31	-	83010s (1)	N/A	N/A
32	-	-	96011s (13824)	95891s (348)
33	-	-	693s (8724)	683s (7603)
34	-	-	854s (732)	854s (732)
35	-	-	31816s (21674)	31792s (19356)

# Conclusions

- ▶ We have demonstrated the power of the SAT+CAS combination by
  - ▶ performing a requested verification of a nonexistence result
  - ▶ generating new matrices for MAGMA's Hadamard database.
- ▶ We are working on extending the system
  - ▶ to search for other types of combinatorial objects
  - ▶ to integrate CAS calls into the inner loop of the SAT solver.
- ▶ Our system is free software and available at  
`sites.google.com/site/uwmathcheck`
