PhD Research Proposal
A SAT+CAS system for checking math conjectures

Curtis Bright

University of Waterloo

March 14, 2016
The research areas of SMT [SAT-Modulo-Theories] solving and symbolic computation are quite disconnected. On the one hand, SMT solving has its strength in efficient techniques for exploring Boolean structures, learning, combining solving techniques, and developing dedicated heuristics, but its current focus lies on easier theories and it makes use of symbolic computation results only in a rather naive way.

Satisfiability checking

Problem statement
Given a logical formula, determine if it is satisfiable.

- A logical formula is an expression involving Boolean variables and logical connectives such as $\land$, $\lor$, $\neg$.
- A formula is satisfiable if there exists an assignment to the variables which make the formula true.
Satisfiability checking

Example

Is \((x \lor y \lor \neg z) \land (\neg x \lor \neg y) \land z\) satisfiable?
Satisfiability checking

Example

Is \((x \lor y \lor \neg z) \land (\neg x \lor \neg y) \land z\) satisfiable?

Yes, as shown by a tree of possible assignments:
**DPLL algorithm**

- **Deduce**: Simplify clauses to detect conflicts and infer new values of variables.
- **Decide**: Choose an unassigned variable and assign it a value.
- **Resolve**: If a conflict occurs, learn a clause prohibiting the current assignment and backjump (undo variable choices leading to the conflict).

![DPLL Algorithm Flowchart](image-url)
DPLL algorithm

Example

Is \((x \lor y \lor \neg z) \land (\neg x \lor \neg y \lor \neg u) \land z \land (\neg y \lor u)\) satisfiable?
DPLL algorithm

Example

Is \((x \lor y \lor \neg z) \land (\neg x \lor \neg y \lor \neg u) \land z \land (\neg y \lor u)\) satisfiable?

Initial clauses

- \(x \lor y \lor \neg z\)
- \(\neg x \lor \neg y \lor \neg u\)
- \(z\)
- \(\neg y \lor u\)
DPLL algorithm

Example
Is \((x \lor y \lor \neg z) \land (\neg x \lor \neg y \lor \neg u) \land z \land (\neg y \lor u)\) satisfiable?

Initial clauses

- \(x \lor y \lor \neg z\)
- \(\neg x \lor \neg y \lor \neg u\)
- \(z\)
- \(\neg y \lor u\)

Deduce
From clause 3, \(z\) must be true. Simplified clauses:

- \(x \lor y\)
- \(\neg x \lor \neg y \lor \neg u\)
- \(\neg y \lor u\)
DPLL algorithm

Decide
Choose $x$ to be true.

- $x \lor y$
- $\neg x \lor \neg y \lor \neg u$
- $\neg y \lor u$
DPLL algorithm

Decide
Choose $x$ to be true.

- $x \lor y$
- $\neg x \lor \neg y \lor \neg u$
- $\neg y \lor u$

Deduce
Propagate the fact that $x$ is true. Simplified clauses:

- $\neg y \lor \neg u$
- $\neg y \lor u$
DPLL algorithm

Decide

Choose \( y \) to be true.

- \(-y \lor \neg u\)
- \(-y \lor u\)
DPLL algorithm

Decide
Choose $y$ to be true.
- $\neg y \lor \neg u$
- $\neg y \lor u$

Deduce
Propagate the fact that $y$ is true. Simplified clauses:
- $\neg u$
- $u$
DPLL algorithm

**Decide**
Choose $y$ to be true.

- $\neg y \lor \neg u$
- $\neg y \lor u$

**Deduce**
Propagate the fact that $y$ is true. Simplified clauses:

- $\neg u$
- $u$

**Resolve**
Conflict: No way to choose $u$. At least one variable assignment must change, so we learn the clause $\neg z \lor \neg x \lor \neg y$. 
DPLL algorithm

Backjump

Clauses after undoing the last variable choice:

- \( \neg y \lor \neg u \)
- \( \neg y \lor u \)
- \( \neg z \lor \neg x \lor \neg y \)
Backjump

Clauses after undoing the last variable choice:

- $\neg y \lor \neg u$
- $\neg y \lor u$
- $\neg z \lor \neg x \lor \neg y$

Deduce

Since $x$ and $z$ are true, clause 3 simplifies to $\neg y$ and $y$ must be false. Simplified clauses: $\emptyset$
DPLL algorithm

Backjump

Clauses after undoing the last variable choice:

- \( \neg y \lor \neg u \)
- \( \neg y \lor u \)
- \( \neg z \lor \neg x \lor \neg y \)

Deduce

Since \( x \) and \( z \) are true, clause 3 simplifies to \( \neg y \) and \( y \) must be false. Simplified clauses: \( \emptyset \)

Satisfying assignment

Take \( x \) true, \( y \) false, and \( z \) true.
SAT-Modulo-Theories (SMT)

It is possible to consider the satisfiability problem for different types of logical formulas, e.g., those of first-order logic over various theories.

- theory of strings
- array theory
- bitvector theory
- theories of arithmetic
  - integer or real
  - linear or nonlinear
Example
Is the formula $x^2 < 0 \lor x^2 > 1$ satisfiable in the integer theory of arithmetic?
Example

Is the formula $x^2 < 0 \lor x^2 > 1$ satisfiable in the integer theory of arithmetic?

Yes, by taking $x = 2$. 
First, translate the given formula into a propositional one:

\[ a \land (x^2 < 0 \lor x^2 > 1) \] becomes \[ a \lor b \]

A SAT solver can then find a satisfying assignment (set \( a \) true).

A theory solver needs to be queried to determine if the assignment yields a solution of the original formula (and if not, why not).

Here the theory solver can produce the clause \( \neg a \) (i.e., \( x^2 \geq 0 \)).
The MathCheck System

- Uses SAT and CAS functionality to finitely verify or counterexample conjectures in mathematics\(^2\).
- Verified two conjectures in graph theory to new bounds.
- Similar to a SMT solver with the theory solver replaced by a CAS.

---

\(^3\) MathCheck2: A SAT+CAS Verifier for Combinatorial Conjectures. Submitted to *IJCAR 2016.*
Contributions

- Demonstration of usefulness of employing SAT to combinatorial conjectures.
- Three general techniques for improving the search.
- Verification that Williamson matrices of order 35 do not exist.
- Description of an algorithm for finding Williamson matrices of a given order (or showing none exist).
- Found 160 Hadamard matrices not in the library of the CAS Magma.
Experimental Results

The result that Williamson matrices of order 35 do not exist was shown in under 9 hours of computation time on SHARCNET\(^4\). This was first shown by Đoković\(^5\), who requested an independent verification.

MathCHECK2 was also able to find Williamson matrices for all orders \(n < 35\).

\(^4\)64-bit AMD Opteron processors running at 2.2 GHz

\(^5\)Williamson matrices of order \(4n\) for \(n = 33, 35, 39\). Discrete Mathematics.
Hadamard matrices

- square matrix with $\pm 1$ entries
- any two distinct rows are orthogonal

Example

\[
H = \begin{bmatrix}
1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 \\
-1 & 1 & 1 & -1 \\
\end{bmatrix}
\]

Conjecture

An $n \times n$ Hadamard matrix exists for any $n$ a multiple of 4.
Verifying $H$ is Hadamard

When $H$ is of order $n$, want to have

$$HH^T = nI_n.$$ 

Need to verify that $\binom{n}{2}$ inner products are 0.

Example

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 \\
-1 & 1 & 1 & -1 \\
-1 & 1 & 1 & -1
\end{bmatrix}
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 \\
1 & -1 & 1 & -1 \\
1 & 1 & -1 & -1 \\
-1 & 1 & 1 & -1 \\
-1 & 1 & 1 & -1
\end{bmatrix}^T = 
\begin{bmatrix}
4 & 0 & 0 & 0 \\
0 & 4 & 0 & 0 \\
0 & 0 & 4 & 0 \\
0 & 0 & 0 & 4
\end{bmatrix}
\]
Williamson Matrices

- $n \times n$ matrices $A$, $B$, $C$, $D$
- entries $\pm 1$
- symmetric, circulant
- $A^2 + B^2 + C^2 + D^2 = 4nI_n$

Example

$$A = B = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \quad C = D = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$$

Williamson construction

A Hadamard matrix of order $4n$ can be constructed from Williamson matrices.
Symmetric and Circulant Matrices

Such matrices are defined by their first $\left\lceil \frac{n+1}{2} \right\rceil$ entries so we may refer to them as if they were sequences.

Examples ($n = 5$ and $6$)

\[
\begin{bmatrix}
a_0 & a_1 & a_2 & a_2 & a_1 \\
a_1 & a_0 & a_1 & a_2 & a_2 \\
a_2 & a_1 & a_0 & a_1 & a_2 \\
a_2 & a_2 & a_1 & a_0 & a_1 \\
a_1 & a_2 & a_2 & a_1 & a_0
\end{bmatrix}
\]

\[
\begin{bmatrix}
a_0 & a_1 & a_2 & a_3 & a_2 & a_1 \\
a_1 & a_0 & a_1 & a_2 & a_3 & a_2 \\
a_2 & a_1 & a_0 & a_1 & a_2 & a_3 \\
a_3 & a_2 & a_1 & a_0 & a_1 & a_2 \\
a_2 & a_3 & a_2 & a_1 & a_0 & a_1 \\
a_1 & a_2 & a_3 & a_2 & a_1 & a_0
\end{bmatrix}
\]

symmetric conditions  circulant conditions
Naive Hadamard Encoding

The property “$H$ is a Hadamard matrix” can be expressed as a logical formula. Each entry of $H$ is represented using a Boolean variable encoding with $\text{BV}(1) = \text{true}$ and $\text{BV}(−1) = \text{false}$. Multiplication becomes XNOR under this encoding, i.e.,

$$\text{BV}(x \cdot y) = \neg (\text{BV}(x) \oplus \text{BV}(y)) \quad \text{for } x, y \in \{±1\}.$$
Naive Hadamard Encoding

Arithmetic formula encoding

\[ \sum_{k=0}^{n-1} h_{ik} \cdot h_{jk} = 0 \quad \text{for all } i \neq j. \]

Boolean variable encoding

Using ‘product’ variables \( p_{ijk} := \neg (\text{BV}(h_{ik}) \oplus \text{BV}(h_{jk})) \) this becomes the cardinality constraints

\[ \left( \# p_{ijk} \text{ true in } \{ p_{ijk} \}_{k=0}^{n-1} \right) = \frac{n}{2} \quad \text{for all } i \neq j. \]
Naive Hadamard Encoding

A binary adder consumes Boolean values and produces Boolean values; when thought of as bits, the outputs contain the binary representation of how many inputs were true.

\[ s = a \oplus b \]
\[ c = a \wedge b \]

Binary adder encoding

In order to encode the cardinality constraints, we use a network of binary adders with \( \{ p_{ijk} \}_{k=0}^{n-1} \) as inputs. The output will be \( \lceil \log_2 n \rceil + 1 \) new variables which store the count of how many inputs are true.
Williamson Encoding

Similar to general encoding, but only using the variables

\ \{(a_i, b_i, c_i, d_i)\}_{i=0}^{[(n-1)/2]}.

Because of the symmetric and circulant properties, only need to verify that the first \(\left\lfloor \frac{n-1}{2} \right\rfloor\) off-diagonal entries of

\[ A^2 + B^2 + C^2 + D^2 \]

are zero. This condition can be rewritten using periodic autocorrelation.
The *periodic autocorrelation function* of the sequence $A$ is

\[ \text{PAF}_A(s) := \sum_{k=0}^{n-1} a_k a_{(k+s) \mod n}. \]

**Periodic and symmetric properties**

- $\text{PAF}_A(s) = \text{PAF}_A(s \mod n)$
- $\text{PAF}_A(s) = \text{PAF}_A(n - s)$
Example

The periodic autocorrelation of \( A = [1, 1, -1, -1, 1] \) is given by:

\[
\begin{align*}
PAF_A(0) &= 1^2 + 1^2 + (-1)^2 + (-1)^2 + 1^2 = 5 \\
PAF_A(1) &= 1^2 + (-1) + (-1)^2 + (-1) + 1^2 = 1 \\
PAF_A(2) &= (-1) + (-1) + (-1) + (-1) + 1^2 = -3 \\
PAF_A(3) &= (-1) + 1^2 + (-1) + (-1) + (-1) = -3 \\
PAF_A(4) &= 1^2 + 1^2 + (-1) + (-1)^2 + (-1) = 1
\end{align*}
\]
Periodic Autocorrelation Function

Example

The periodic autocorrelation of \( A = [1, 1, -1, -1, 1] \) is given by:

\[
\begin{align*}
\text{PAF}_A(0) &= 1^2 + 1^2 + (-1)^2 + (-1)^2 + 1^2 = 5 \\
\text{PAF}_A(1) &= 1^2 + (-1) + (-1)^2 + (-1) + 1^2 = 1 \\
\text{PAF}_A(2) &= (-1) + (-1) + (-1) + (-1) + 1^2 = -3 \\
\text{PAF}_A(3) &= (-1) + 1^2 + (-1) + (-1) + (-1) = -3 \\
\text{PAF}_A(4) &= 1^2 + 1^2 + (-1) + (-1)^2 + (-1) = 1
\end{align*}
\]
Periodic Autocorrelation Function

Example

The periodic autocorrelation of $A = [1, 1, -1, -1, 1]$ is given by:

$$PAF_A(0) = 1^2 + 1^2 + (-1)^2 + (-1)^2 + 1^2 = 5$$
$$PAF_A(1) = 1^2 + (-1) + (-1)^2 + (-1) + 1^2 = 1$$
$$PAF_A(2) = (-1) + (-1) + (-1) + (-1) + 1^2 = -3$$
$$PAF_A(3) = (-1) + 1^2 + (-1) + (-1) + (-1) = -3$$
$$PAF_A(4) = 1^2 + 1^2 + (-1) + (-1)^2 + (-1) = 1$$
Periodic Autocorrelation Function

Example

The periodic autocorrelation of $A = [1, 1, -1, -1, 1]$ is given by:

\[
\begin{align*}
\text{PAF}_A(0) &= 1^2 + 1^2 + (-1)^2 + (-1)^2 + 1^2 &= 5 \\
\text{PAF}_A(1) &= 1^2 + (-1) + (-1)^2 + (-1) + 1^2 &= 1 \\
\text{PAF}_A(2) &= (-1) + (-1) + (-1) + (-1) + 1^2 &= -3 \\
\text{PAF}_A(3) &= (-1) + 1^2 + (-1) + (-1) + (-1) &= -3 \\
\text{PAF}_A(4) &= 1^2 + 1^2 + (-1) + (-1)^2 + (-1) &= 1
\end{align*}
\]
Example

The periodic autocorrelation of $A = [1, 1, -1, -1, 1]$ is given by:

$$PAF_A(0) = 1^2 + 1^2 + (-1)^2 + (-1)^2 + 1^2 = 5$$
$$PAF_A(1) = 1^2 + (-1) + (-1)^2 + (-1) + 1^2 = 1$$
$$PAF_A(2) = (-1) + (-1) + (-1) + (-1) + 1^2 = -3$$
$$PAF_A(3) = (-1) + 1^2 + (-1) + (-1) + (-1) = -3$$
$$PAF_A(4) = 1^2 + 1^2 + (-1) + (-1)^2 + (-1) = 1$$
Williamson Encoding

The $s$th entry of

$$A^2 + B^2 + C^2 + D^2$$

is

$$\text{PAF}_A(s) + \text{PAF}_B(s) + \text{PAF}_C(s) + \text{PAF}_D(s).$$

To verify $A, B, C, D$ are Williamson matrices, we want to verify that this is 0 for $s = 1, \ldots, \left\lfloor \frac{n-1}{2} \right\rfloor$. 
Compression

The $m$-compression of a sequence $A = [a_0, \ldots, a_{n-1}]$ of length $n = dm$ is the sequence of length $d$

$$A^{(d)} := [a_0^{(d)}, \ldots, a_{d-1}^{(d)}]$$

where $a_j^{(d)} := \sum_{k=0}^{m-1} a_{j+k \cdot d}$.

Example

The sequence $A = [a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9]$ has the 5-compression

$$[a_0 + a_2 + a_4 + a_6 + a_8, \ a_1 + a_3 + a_5 + a_7 + a_9]$$

and the 2-compression

$$[a_0 + a_5, \ a_1 + a_6, \ a_2 + a_7, \ a_3 + a_8, \ a_4 + a_9].$$
Compression

The \textit{m-compression} of a sequence \(A = [a_0, \ldots, a_{n-1}]\) of length \(n = dm\) is the sequence of length \(d\)

\[
A^{(d)} := [a_0^{(d)}, \ldots, a_{d-1}^{(d)}] \quad \text{where} \quad a_j^{(d)} := \sum_{k=0}^{m-1} a_{j+kd}.
\]

Example

The sequence \(A = [a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9]\) has the 5-compression

\[
[a_0 + a_2 + a_4 + a_6 + a_8, \ a_1 + a_3 + a_5 + a_7 + a_9]
\]

and the 2-compression

\[
[a_0 + a_5, \ a_1 + a_6, \ a_2 + a_7, \ a_3 + a_8, \ a_4 + a_9].
\]
Useful Properties of Compressed Sequences

Lemma 1
Let $A$ be a $\pm 1$-sequence of length $n = dm$. The entries of the $m$-compression of $A$ have absolute value at most $m$ and have the same parity as $m$.

Lemma 2
The compression of a symmetric sequence is also symmetric.
Technique 1: Sum-of-squares Decomposition

Full compression

Let $A, B, C, D$ be Williamson sequences with $n$-compressions $A', B', C', D'$. A theorem of Đoković–Kotsireas\(^6\) says that

$$\text{PAF}_{A'}(0) + \text{PAF}_{B'}(0) + \text{PAF}_{C'}(0) + \text{PAF}_{D'}(0) = 4n$$

which is just

$$\text{rowsum}(A)^2 + \text{rowsum}(B)^2 + \text{rowsum}(C)^2 + \text{rowsum}(D)^2 = 4n.$$ 

Also, each rowsum has the same parity as $n$ by Lemma 1.

\(^6\)Compression of periodic complementary sequences and applications. Designs, Codes and Cryptography.
Why is this useful?

CAS functions exist which can determine all possible solutions of

\[ w^2 + x^2 + y^2 + z^2 = 4n \quad w, x, y, z \equiv n \pmod{2}. \]

This tells us all possibilities for the rowsums of \( A, B, C, D \). We can then use binary adders to encode the constraints

\[
\begin{align*}
\text{rowsum}(A) &= w \\
\text{rowsum}(B) &= x \\
\text{rowsum}(C) &= y \\
\text{rowsum}(D) &= z.
\end{align*}
\]
Example

When \( n = 35 \), there are exactly three ways to write \( 4n \) as a sum of four positive odd squares in ascending order:

\[
1^2 + 3^2 + 3^2 + 11^2 = 4 \cdot 35 \\
1^2 + 3^2 + 7^2 + 9^2 = 4 \cdot 35 \\
3^2 + 5^2 + 5^2 + 9^2 = 4 \cdot 35
\]
Williamson Equivalence Operations

1. Ordering

The Williamson matrices $A$, $B$, $C$, $D$ can be re-ordered with impunity. Given this, we may enforce the constraint

$$|\text{rowsum}(A)| \leq |\text{rowsum}(B)| \leq |\text{rowsum}(C)| \leq |\text{rowsum}(D)|.$$
Williamson Equivalence Operations

2. Negation

The entries in any Williamson matrix $A, B, C, D$ may be negated without affecting the Williamson conditions. Given this, we may enforce the constraint

$$0 \leq \text{rowsum}(X) \quad \text{for } X = A, B, C, D.$$
Williamson Equivalence Operations

2. Negation

The entries in any Williamson matrix $A, B, C, D$ may be negated without affecting the Williamson conditions. Given this, we may enforce the constraint

$$0 \leq \text{rowsum}(X) \quad \text{for } X = A, B, C, D.$$ 

Alternatively, when $n$ is odd, we can use

$$\text{rowsum}(X) \equiv n \pmod{4} \quad \text{for } X = A, B, C, D.$$ 

In this case, Williamson showed that $a_i b_i c_i d_i = -1$ for all $1 \leq i \leq n - 1$. 
Technique 2: Divide-and-conquer

For efficiency reasons, we want to partition the search space into subspaces. An effective way to do this is to have each subspace contain one possibility for the compressions of $A$, $B$, $C$, $D$.

The generator script uses Lemmas 1 and 2 to determine all possible compressions, and the ĐK theorem to remove possibilities whose uncompressions are necessarily invalid (for example, because their power spectral density is too large).
Power Spectral Density

The *power spectral density* of a sequence $A$ is

$$PSD_A(s) := |DFT_A(s)|^2$$

where $DFT_A$ is the *discrete Fourier transform* of $A$.

**Example**

The power spectral density of $A = [1, 1, -1, -1, 1]$ is given by:

- $PSD_A(0) = 1^2 = 1$
- $PSD_A(1) \approx 3.236^2 = 10.472$
- $PSD_A(2) \approx (-1.236)^2 = 1.528$
- $PSD_A(3) \approx (-1.236)^2 = 1.528$
- $PSD_A(4) \approx 3.236^2 = 10.472$
Đoković–Kotsireas Theorem

Let $A$, $B$, $C$, $D$ be Williamson sequences. For all $s \in \mathbb{Z}$

$$\text{PSD}_A(s) + \text{PSD}_B(s) + \text{PSD}_C(s) + \text{PSD}_D(s) = 4n$$

and these still hold if $A$, $B$, $C$, $D$ are replaced with their compressions.

**Corollary**

If $\text{PSD}_X(s) > 4n$ for some $s$ then $X$ (or any sequence which compresses to $X$) cannot be a Williamson sequence.
Technique 2: Divide-and-conquer

For \( n = 35 \) with 7-compression, the following is one of 41 compressions which satisfy the ĐK condition:

\[
\begin{align*}
A^{(5)} &= [\ 5, \ 1, -3, -3, \ 1] \\
B^{(5)} &= [-3, \ 3, -3, -3, \ 3] \\
C^{(5)} &= [-3, \ 1, -1, -1, \ 1] \\
D^{(5)} &= [1, -3, -3, -3, -3]
\end{align*}
\]
Technique 2: Divide-and-conquer

If \( n \) has more than one nontrivial factor it is possible to perform compression by both factors. This increases the number of subspaces, but decreases the size of each subspace.

**Example**

Using 5 and 7-compression on \( n = 35 \) lead to the following number of subspaces for each decomposition type:

<table>
<thead>
<tr>
<th>Instance type</th>
<th># subspaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 1^2 + 3^2 + 3^2 + 11^2 )</td>
<td>6960</td>
</tr>
<tr>
<td>( 1^2 + 3^2 + 7^2 + 9^2 )</td>
<td>8424</td>
</tr>
<tr>
<td>( 3^2 + 5^2 + 5^2 + 9^2 )</td>
<td>6290</td>
</tr>
</tbody>
</table>
Technique 3: UNSAT Core

When an instance is found to be unsatisfiable, some SAT solvers can generate an *UNSAT core* containing which of those variables lead to the UNSAT result. We can prune instances which set the same variables to the same values.

**Example**

The $n = 35$ instances contained 3376 variables but only 168 were set differently between instances (those which encode the rowsum and compression values).
Experimental Results

Timings on SHARCNET for Williamson orders $25 \leq n \leq 35$ are below. The number of SAT calls which successfully returned a result is in parenthesis. A hyphen denotes a timeout after 24h.

<table>

Future Work

1. Extend Hadamard results

- Search larger orders and find new inequivalent Hadamard matrices.
- Explore different construction types, such as Hadamard matrices with (one or two) circulant cores. These are defined with a similar number of variables as the Williamson construction and the second type is conjectured to exist for all orders $4n$ (Kotsireas et al.\textsuperscript{7}).
- Extend our system to find all inequivalent matrices of a given order. Currently, the number of inequivalent Williamson matrices is known only for odd $n < 60$.

\textsuperscript{7}Hadamard ideals and Hadamard matrices with two circulant cores. *European Journal of Combinatorics.*
Future Work

2. Support other conjectures

- Search for other combinatorial objects which can be defined using the autocorrelation function; Kotsireas lists at least 11 different types:

<table>

Future Work

2. Support other conjectures

▶ Some use the *aperiodic* autocorrelation function, defined by

\[
\text{AAF}_A(s) := \sum_{k=0}^{n-s-1} a_k \bar{a}_{k+s} \quad \text{for } s = 0, \ldots, n - 1.
\]

▶ For example, complex Golay sequences are two sequences \(A, B \in \{\pm 1, \pm i\}^n\) which satisfy

\[
\text{AAF}_A(s) + \text{AAF}_B(s) = 0 \quad \text{for } s = 1, \ldots, n - 1.
\]
Future Work

3. Extend SAT solver programmatically

- Make custom modifications to the SAT solvers used to run domain-specific code tailored to each conjecture.
- Ganesh et al.\(^9\) introduced a special API for programmatically influencing the behaviour of a SAT solver by generating problem-specific learned clauses as the search progresses. This approach was shown to be up to 100 times more efficient in the context of RNA folding problems.
- Benefits include increased expressiveness, efficiency, and better leverage of CAS functionality.

Future Work

3. Extend SAT solver programmatically

Example 1

The Williamson instances required encoding constraints like \( \text{rowsum}(A) = 1 \) from which we can determine how many of \( a_0, \ldots, a_{n-1} \) must be true.

We can have the SAT solver keep track of this count and backjump whenever a partial assignment is inconsistent with the constraint.
Williamson Equivalence Operations

3. Permuting entries

We can reorder the entries of the generating matrices with the rule $a_i \mapsto a_{ki \mod n}$ where $k$ is any number coprime with $n$, and similarly for $b_i$, $c_i$, $d_i$ (the same reordering must be applied to each).
Future Work

3. Extend SAT solver programmatically

Example 2

Calling CAS functions from inside the SAT solver will allow theory-specific lemmas to be learned, such as those detecting symmetries and pruning isomorphic solutions.

The Williamson equivalence operation of permuting entries would be difficult to encode using propositional formulae but can be easily computed by a CAS.
Conclusions

We have...

- Presented the advantages of utilizing the power of SAT solvers in combination with domain specific knowledge and algorithms provided by computer algebra systems.
- Outlined how such a strategy can be useful for studying a wide variety of conjectures in combinatorics, and potential ways to improve such a strategy.
- Performed a requested verification of a nonexistence result using a new algorithm and techniques which generalize to other conjectures.
- Submitted new matrices to MAGMA’s Hadamard database, including some generated by Williamson matrices of even order.
