Solving Problems by Searching

CS 486/686: Introduction to Artificial Intelligence
Introduction

• Search was one of the first topics studied in AI
  - Newell and Simon (1961) *General Problem Solver*

• Central component to many AI systems
  - Automated reasoning, theorem proving, robot navigation, scheduling, game playing,...
A search problem consists of:

- a state space
- a successor function (actions, cost)

\[ (N, 1.0) \quad (E, 1.0) \]

- a start state and a goal test

A solution is a sequence of actions (plan) from the start state to a goal state.
Example: Traveling in Romania

• States:
• Initial State:
• Successor Function:
• Goal test:
• Solution:
Examples of Search Problems

- States:
- Initial State:
- Successor Function:
- Goal test:
- Solution:

- Successor Function:
- Goal test:
- Solution:
Examples of Search Problems
Our Definition Excludes...

- Chance
- Continuous states
- Partial Observability
- Adversaries
- All of the above
What is a state space?

The **world state** includes every last detail of the environment.

A **search state** keeps only the details needed for planning (abstraction).

- **Problem: Pathing**
  - States: (x, y) location
  - Actions: NSEW
  - Successor: update location only
  - Goal test: is (x, y) = END

- **Problem: Eat-All-Dots**
  - States: {(x, y), dot booleans}
  - Actions: NSEW
  - Successor: update location and possibly a dot boolean
  - Goal test: dots all false

Adapted from UC Berkeley’s CS188 Course
Representing Search

- **State space graph**
  - Vertices correspond to states (one vertex for each state)
  - Edges correspond to successors
  - Goal test is a set of goal nodes

- We search for a solution by building a search tree and traversing it to find a goal state
**Search Tree**

- **A search tree:**
  - Start state is the root of the tree
  - Children are successors
  - A plan is a path in the tree. A solution is a path from the root to a goal node.
  - For most problems we do not actually generate the entire tree
Quiz

• Given this state graph, how large is the search tree?
Expanding Nodes

- Expanding a node
  - Applying all legal operators to the state contained in the node
  - Generating nodes for all corresponding successor states
Example: Traveling in Romania
Generic Search Algorithm

- Initialize with initial state of the problem
- Repeat
  - If no candidate nodes can be expanded, return failure
  - Choose leaf node for expansion, according to search strategy
  - If node contains goal state, return solution
  - Otherwise, expand the node. Add resulting nodes to the tree
Implementation Details
Search Strategies

Adapted from UC Berkeley's CS188 Course
Search Strategies
Depth-First Search

**Strategy:** Expand deepest node first  
**Implementation:** LIFO stack
Key Properties

- **Completeness**: Is the alg. guaranteed to find a solution if the solution exists?
- **Optimality**: Does the alg. find the optimal solution?
- **Time complexity**
- **Space complexity** (size of the fringe)

- \( b \): branching factor
- \( m \): maximum depth
- \( d \): depth of shallowest goal node

Number of nodes in tree? \( 1 + b + b^2 + \ldots + b^m = O(b^m) \)
DFS Properties

• Complete?
• Optimal?
• Time complexity
• Space complexity

Diagram:
- 1 node
- $b$ nodes
- $b^2$ nodes
- $b^m$ nodes

$m$ tiers
Breadth-First Search

**Strategy:** Expand shallowest node first

**Implementation:** FIFO queue
BFS Properties

• Complete?
• Optimal?
• Time complexity
• Space complexity
Quiz: DFS vs BFS
Iterative Deepening Search

- Can we combine search methods to take advantage of DFS space complexity and BFS completeness/shallow solution advantage?

![Diagram showing iterative deepening search on a binary tree.](image)
IDS Properties

• Complete?

• Optimal?

• Time complexity

• Space complexity

Wasteful? Most nodes found in lowest level of search so not too bad
Recall that BFS was only optimal under some conditions (i.e. we only cared about number of actions taken). What can we do if actions have different costs?
Uniform Cost Search

Strategy: Expand cheapest node first
Implementation: Priority queue
UCS Properties

• Complete?
• Optimal?
• Time complexity
• Space complexity
Summary

• These algorithms are basically the same except for the order in which they expand nodes
  • Basically all priority queues with different ways to determining priorities

• How successful the search is depends heavily on your model!
Questions?

• Next class: Informed search
