

Informed Search

CS 486/686: Introduction to Artificial Intelligence

Outline

- Using knowledge
 - Heuristics
- Best-first search
 - Greedy best-first search
 - A* search
 - Variations of A*
- Back to heuristics

Last lecture

- Uninformed search uses no knowledge about the problem
 - Expands nodes based on “distance” from start node (never looks ahead to goal)
- Pros
 - Very general
- Cons
 - Very expensive
- Non-judgmental
 - Some are complete, some are not

Informed Search

- We often have additional **knowledge** about the problem
 - Knowledge is often **merit of a node** (value of a node)
 - Example: Romania travel problem?
- Different notions of merit
 - **Cost of solution**
 - Minimizing computation

Uninformed vs Informed Search

- Uninformed search expands nodes based on distance from start node, $d(n_{\text{start}}, n)$
- Why not expand on distance to goal, $d(n, n_{\text{goal}})$?

Heuristics

- A heuristic is a function that **estimates** the cost of reaching a goal from a given state

Examples:

- Euclidean distance
- Manhattan distance

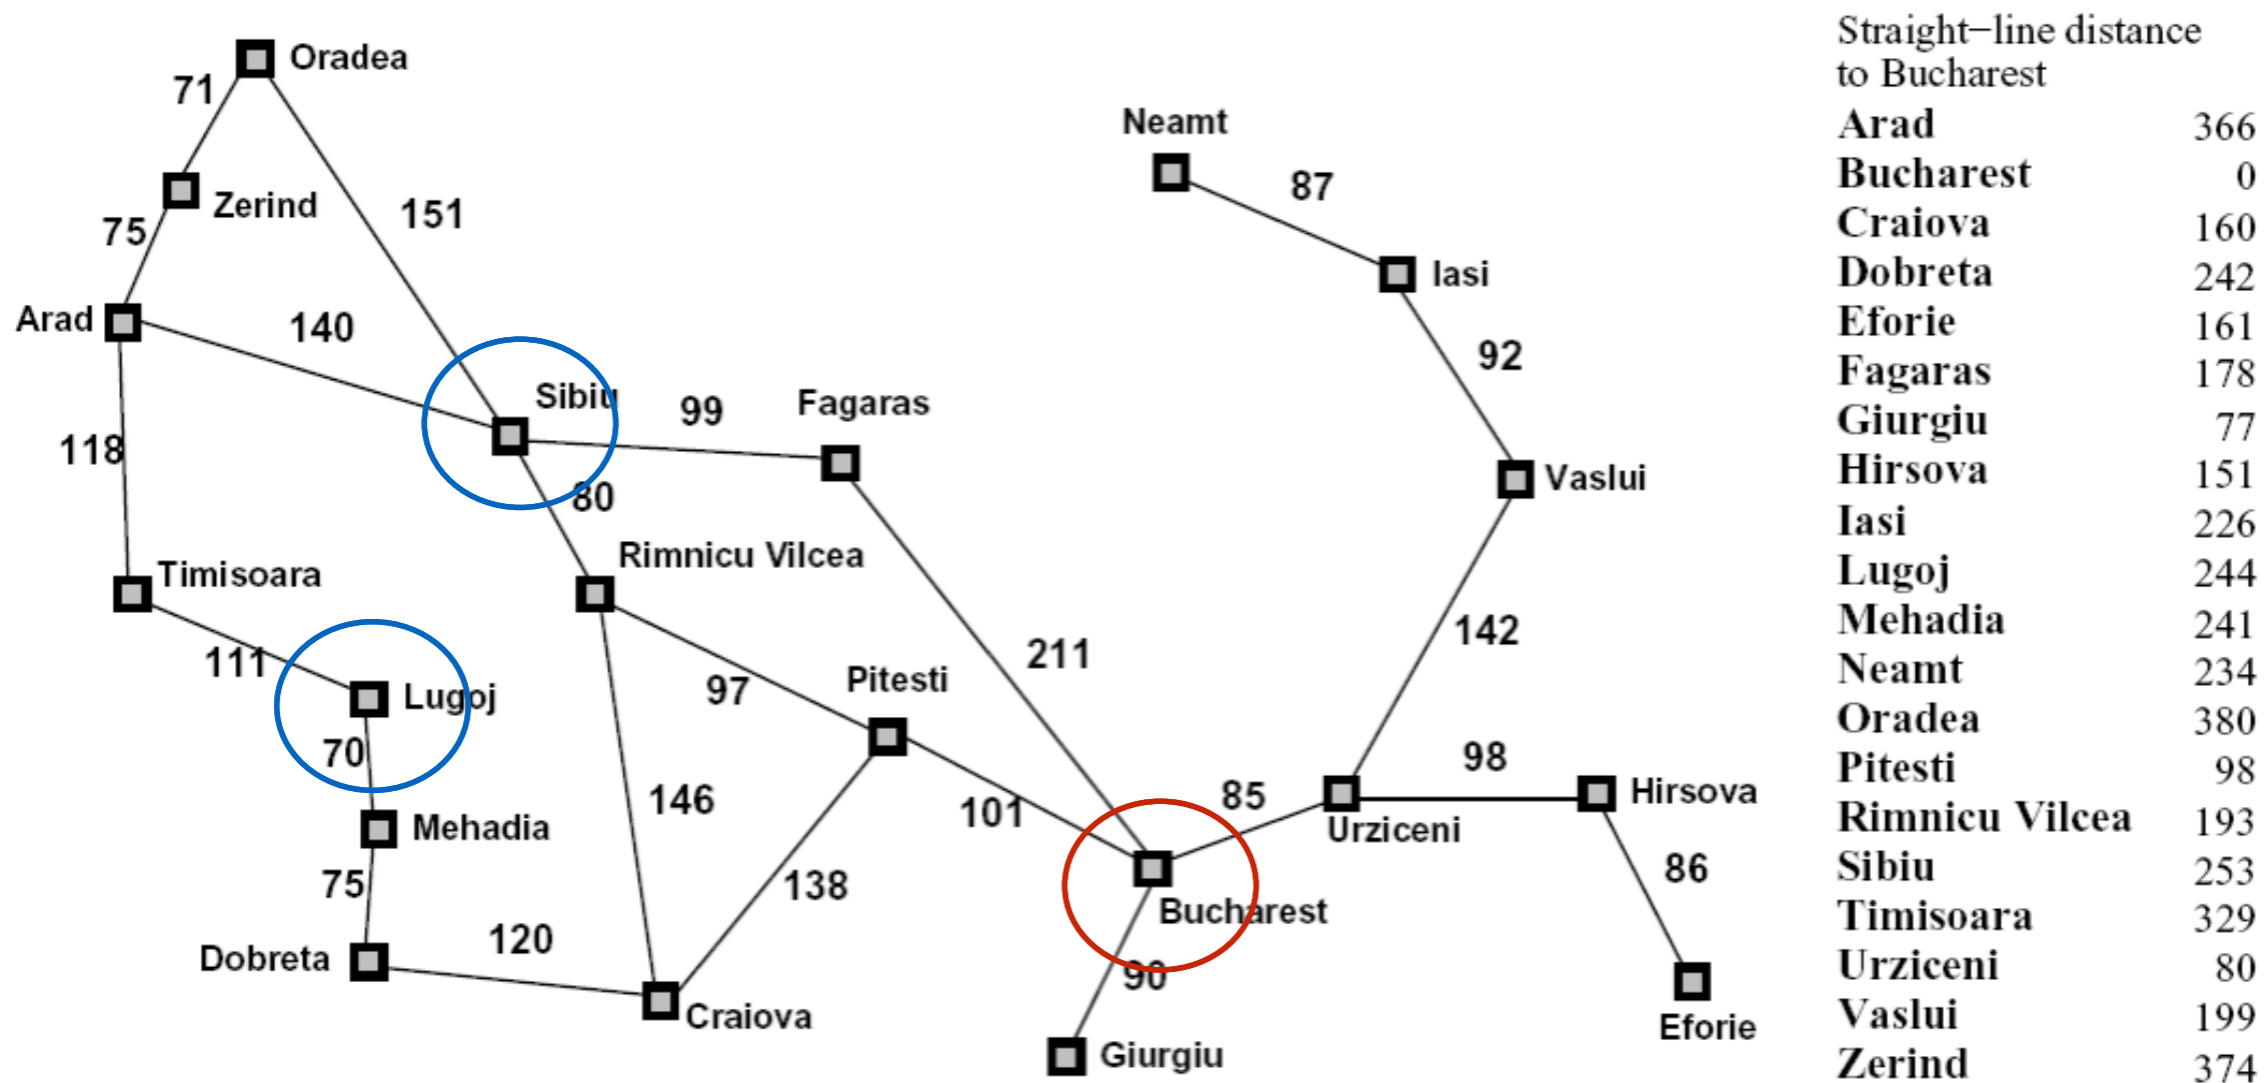

Example

h(x)

Heuristics: Structure

- If $h(n_1) < h(n_2)$ we guess it is cheaper to reach the goal from n_1 than n_2
- We require $h(n_{goal}) = 0$

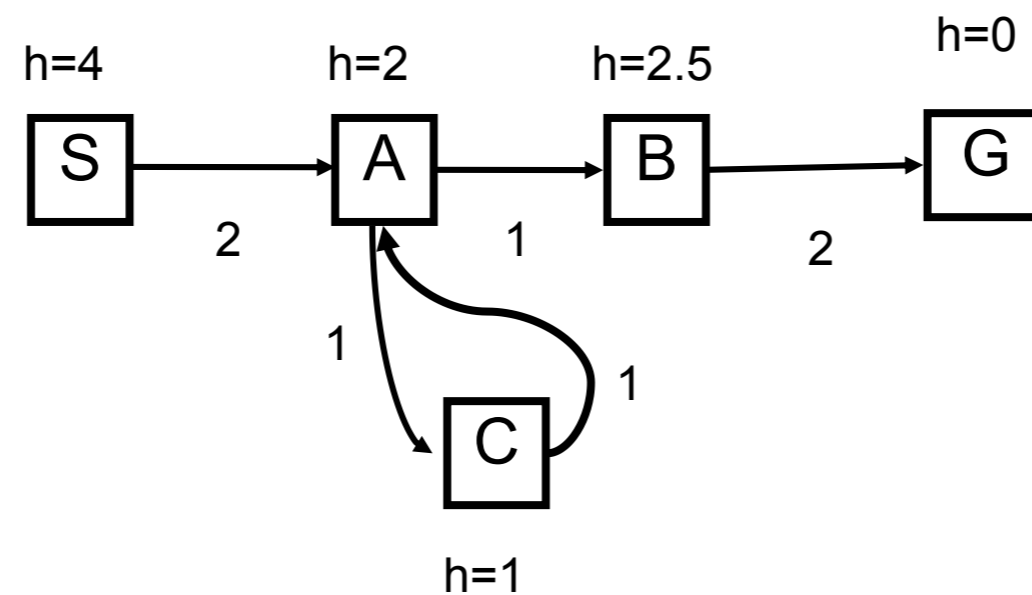

Example: Best First search

Search strategy: Expand the most promising node according to the heuristic

Example: Best First Search

Best First Search Properties

- **Complete?**
- **Optimal?**
- **Time complexity**
- **Space complexity**

A* Search

- Observations
 - Best first search ordered nodes by ***forward cost to goal***, $h(n)$
 - Uniform cost search ordered nodes by ***backward cost of path so far***, $g(n)$
- A* search
 - Expand nodes in order $f(n)=g(n)+h(n)$

Example: A* search

When Should A* Terminate?

A* and Revisiting States

Is A* Optimal?

Admissible Heuristics

A heuristic, h , is ***admissible*** if

$$0 \leq h(n) \leq h^*(n)$$

for all n , where $h^*(n)$ is the (true) shortest path from n to any goal state

Admissible heuristics are optimistic.

Note that $h(n)=0$ is admissible.

Optimality of A^*

If the heuristic is admissible then A^* with **tree-search** is optimal

Why?

Optimality of A*

- For **graphs** we require consistency
 - $h(n) \leq \text{cost}(n, n') + h(n')$
 - Almost any admissible heuristic function will also be consistent
- A* search on graphs with a consistent heuristic is optimal

A* Search Properties

- **Complete?**

- **Optimal?**

- **Time complexity**

- **Space complexity**

Heuristic Functions

- A good heuristic function can make all the difference!
- How do we get heuristics?

8 Puzzle

- Relax the game
 1. Can move from A to B if A is next to B
 2. Can move from A to B if B is blank
 3. Can move from A to B

8 Puzzle

- Can move from A to B:
(*Misplaced Tile Heuristic, h1*)
- Admissible?
- Can move from A to B if B is next to A:(*Manhattan Distance Heuristic, h2*)
- Admissible?

Which is the better heuristic?
(Which one dominates?)

8 Puzzle and Heuristics

Depth	IDS	A*(h₁)	A*(h₂)
2	10	6	6
4	112	13	12
8	6384	39	25
12	3644035	227	73
24	-	39135	1641

Designing Heuristics

- Relax the problem
- Precompute solution costs of subproblems and storing them in a pattern database
- Learning from experience with the problem class
- ...

Often there is a **tradeoff** between accuracy of your heuristic (and thus the amount of search) and the amount of computation you must do to compute it

Summary

- What you should know
 - Thoroughly understand A^*
 - Be able to trace simple examples of A^* execution
 - Understand admissibility of heuristics
 - Completeness, optimality

Memory-Bounded Heuristic Search

- Iterative Deepening A^* (IDA*)
 - Basically depth-first search but using the f-value to decide which order to consider nodes
 - Use f-limit instead of depth limit
 - New f-limit is the smallest f-value of any node that exceeded cutoff on previous iteration
 - Additionally keep track of next limit to consider
 - IDA* has same properties as A^* but uses less memory

Memory-Bounded Heuristic Search

- Simplified Memory-Bounded A* (SMA*)
 - Uses all available memory
 - Proceeds like A* but when it runs out of memory it drops the worst leaf node (one with highest f-value)
 - If all leaf nodes have same f-value, drop oldest and expand newest
 - Optimal and complete if depth of shallowest goal node is less than memory size
