

# Constraint Satisfaction

CS 486/686: Introduction to Artificial Intelligence

# Outline

What are Constraint Satisfaction Problems (CSPs)?

Standard Search and CSPs

Improvements

Backtracking

Backtracking + heuristics

Forward Checking

# Introduction

## Standard search

**State** is a “black box”: arbitrary data structure

**Goal test:** any function over states

**Successor function:** anything that lets you move from one state to another

## Constraint satisfaction problems (CSPs)

A special subset of search problems

**States** are defined by *variables*  $X_i$  with values from *domains*  $D_i$

**Goal test** is a *set of constraints* specifying allowable combinations of values for subsets of variables

# Example: Map Colouring

## Variables

$V = \{T, V, NSW, Q, NT, WA, SA\}$

## Domains

$D = \{\text{red, blue, green}\}$

**Constraints:** adjacent regions must have different colours

Implicit:  $WA \neq NT$

Explicit:  $(WA, NT) \in \{(\text{red, blue}), (\text{red, green}), (\text{blue, red})\dots\}$

**Solution** is an assignment satisfying all constraints

$\{WA = \text{red}, NT = \text{green}, Q = \text{red}, NSW = \text{green}, V = \text{red}, SA = \text{blue}, T = \text{green}\}$

# N Queens Problem

**Variables:**  $X_{i,j}$

**Domains:**  $\{0,1\}$

**Constraints:**

$$\forall i, j, k \quad (X_{ij}, X_{ik}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{kj}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{i+k, j+k}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{i+k, j-k}) \in \{(0, 0), (0, 1), (1, 0)\}$$

# N Queens Problem

**Variables:**  $Q_i$

**Domains:**  $\{1, 2, \dots, N\}$

**Constraints:**

Implicit:

$$\forall i, j \text{ non-threatening}(Q_i, Q_j)$$

Explicit:

$$(Q_1, Q_2) \in \{(1, 3), (1, 4), \dots\}$$

...

# 3 Sat

**Variables:**  $V_1, \dots, V_n$

**Domains:**  $\{0,1\}$

**Constraints:**

K constraints of the form  $V_i^* \vee V_j^* \vee V_k^*$  where  $V_i^*$  is either  $V_i$  or  $\neg V_i$

$$A \neg B \vee \neg C$$

$$\neg A \vee B \vee D$$

$$D \vee B \vee E$$

$$\neg A \vee \neg B \vee C$$

A canonical NP-complete  
problem

# Types of CSPs

## Discrete Variables

### Finite domains

If domain has size  $d$ , then there are  $O(d^n)$  complete assignments  
Boolean CSPs (including 3-SAT)

### Infinite domains (e.g. integers)

Constraint languages

Linear constraints are solvable but non-linear are undecidable

## Continuous Variables

Linear programming (linear constraints solvable in polynomial time)

# Types of CSPs

## Varieties of Constraints

**Unary constraints:** involve a single variable

NSW≠red

**Binary constraints:** involve a pair of variables

NSW≠Q

**Higher-order constraints:** involve more than two variables

AllDiff( $V_1, \dots, V_n$ )

## Soft Constraints (preferences)

red “is better than” green

Constrained optimization problems

# Constraint Graphs

You can represent binary constraints with a constraint graph

Nodes are variables

Edges are constraints

# CSPs and Search

We can use standard search to solve CSPs

States:

Initial State:

Successor Function:

Goal Test:

# CSPs and Search

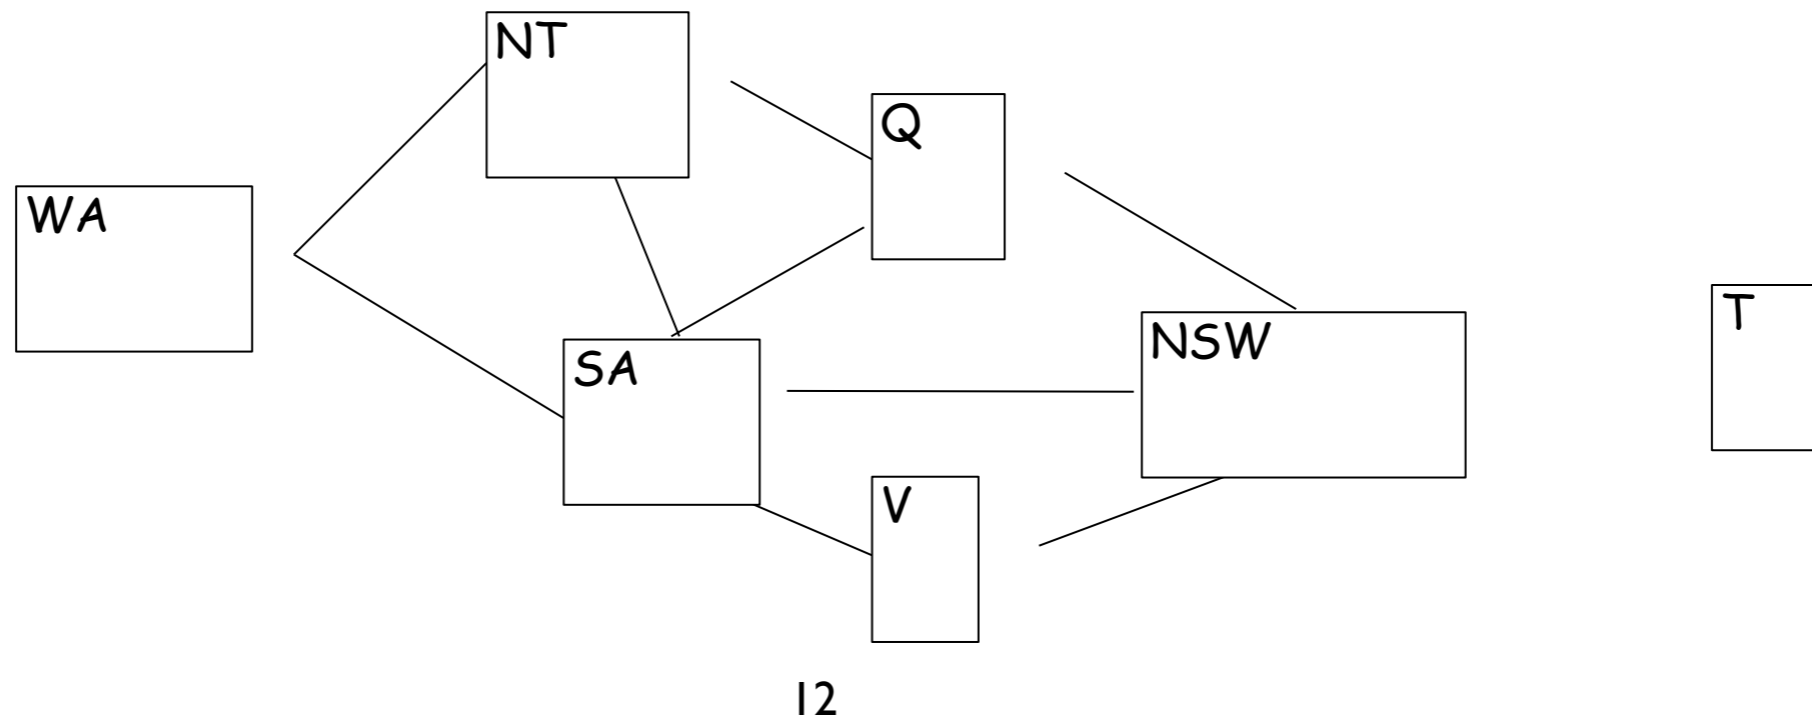

States:

Initial State:

Successor Function:

Goal Test:

**What happens if we run something like BFS?**

# Commutativity

## Key Insight: CSPs are commutative

- Order of actions does not effect outcome
- Can assign variables in any order

{WA=red, NT=blue}  
is equivalent to  
{NT=blue, WA=red}

## CSP algorithms take advantage of this

- Consider assignment of a single variable at each node in the tree

# Backtracking Search

Backtracking search is the basic algorithm for CSPs

Select unassigned variable  $X$

For each value  $\{x_1, \dots, x_n\}$  in domain of  $X$

**One variable at a time**

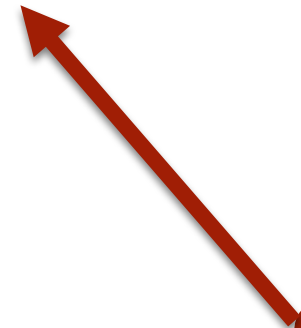

If value satisfies constraints, assign  $X=x_i$  and exit loop

If an assignment is found

Move to next variable

If no assignment found

**Check constraints as you go**

**Back up** to preceding variable and try a different assignment for it

# Backtracking Example

0

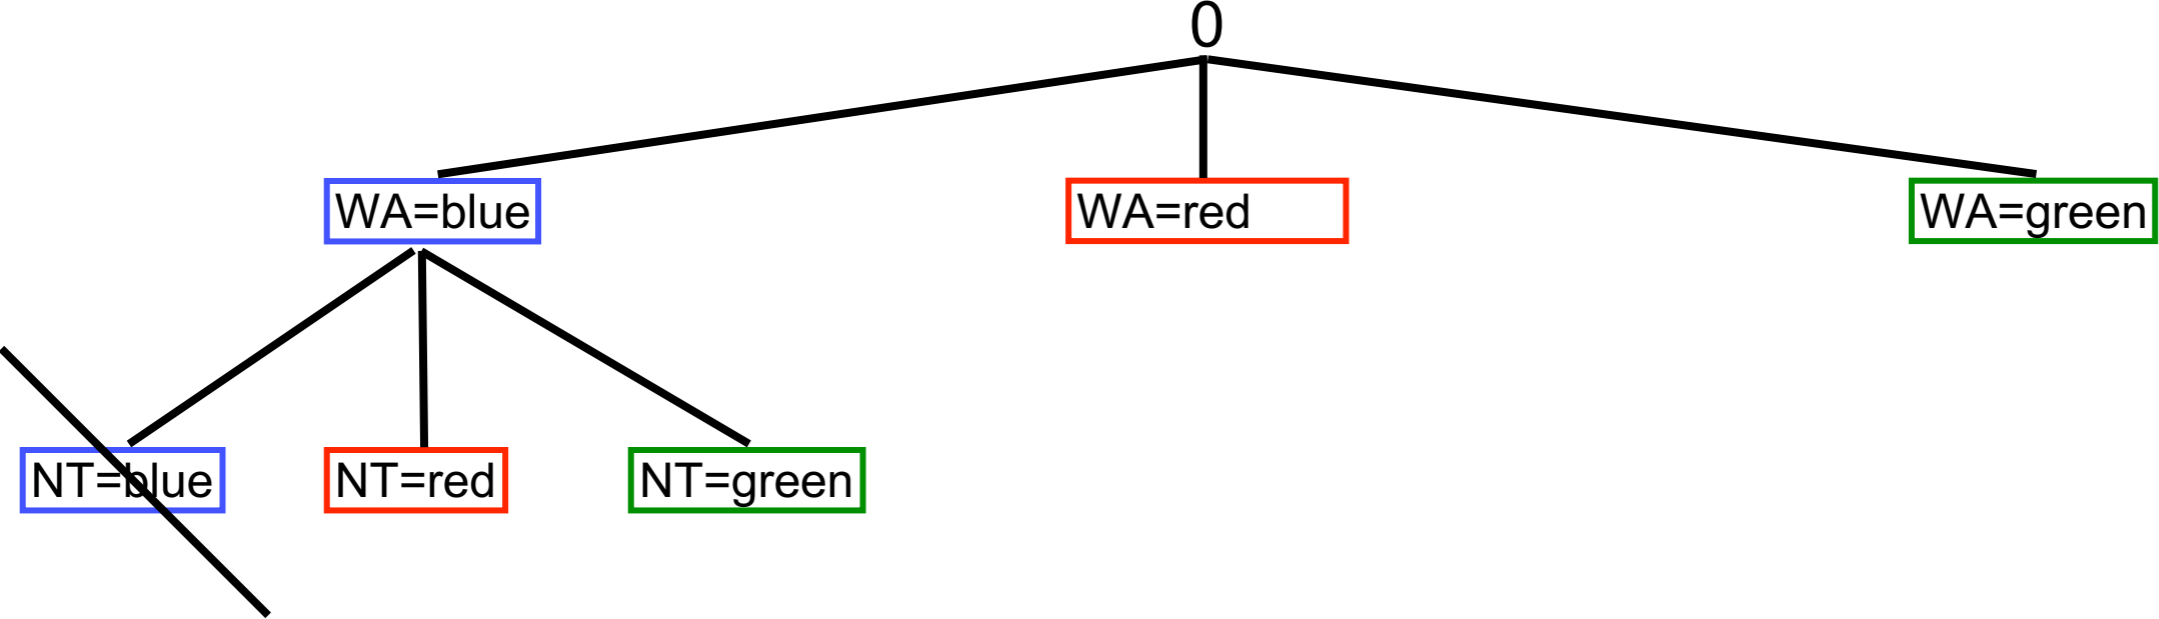

# Backtracking Example

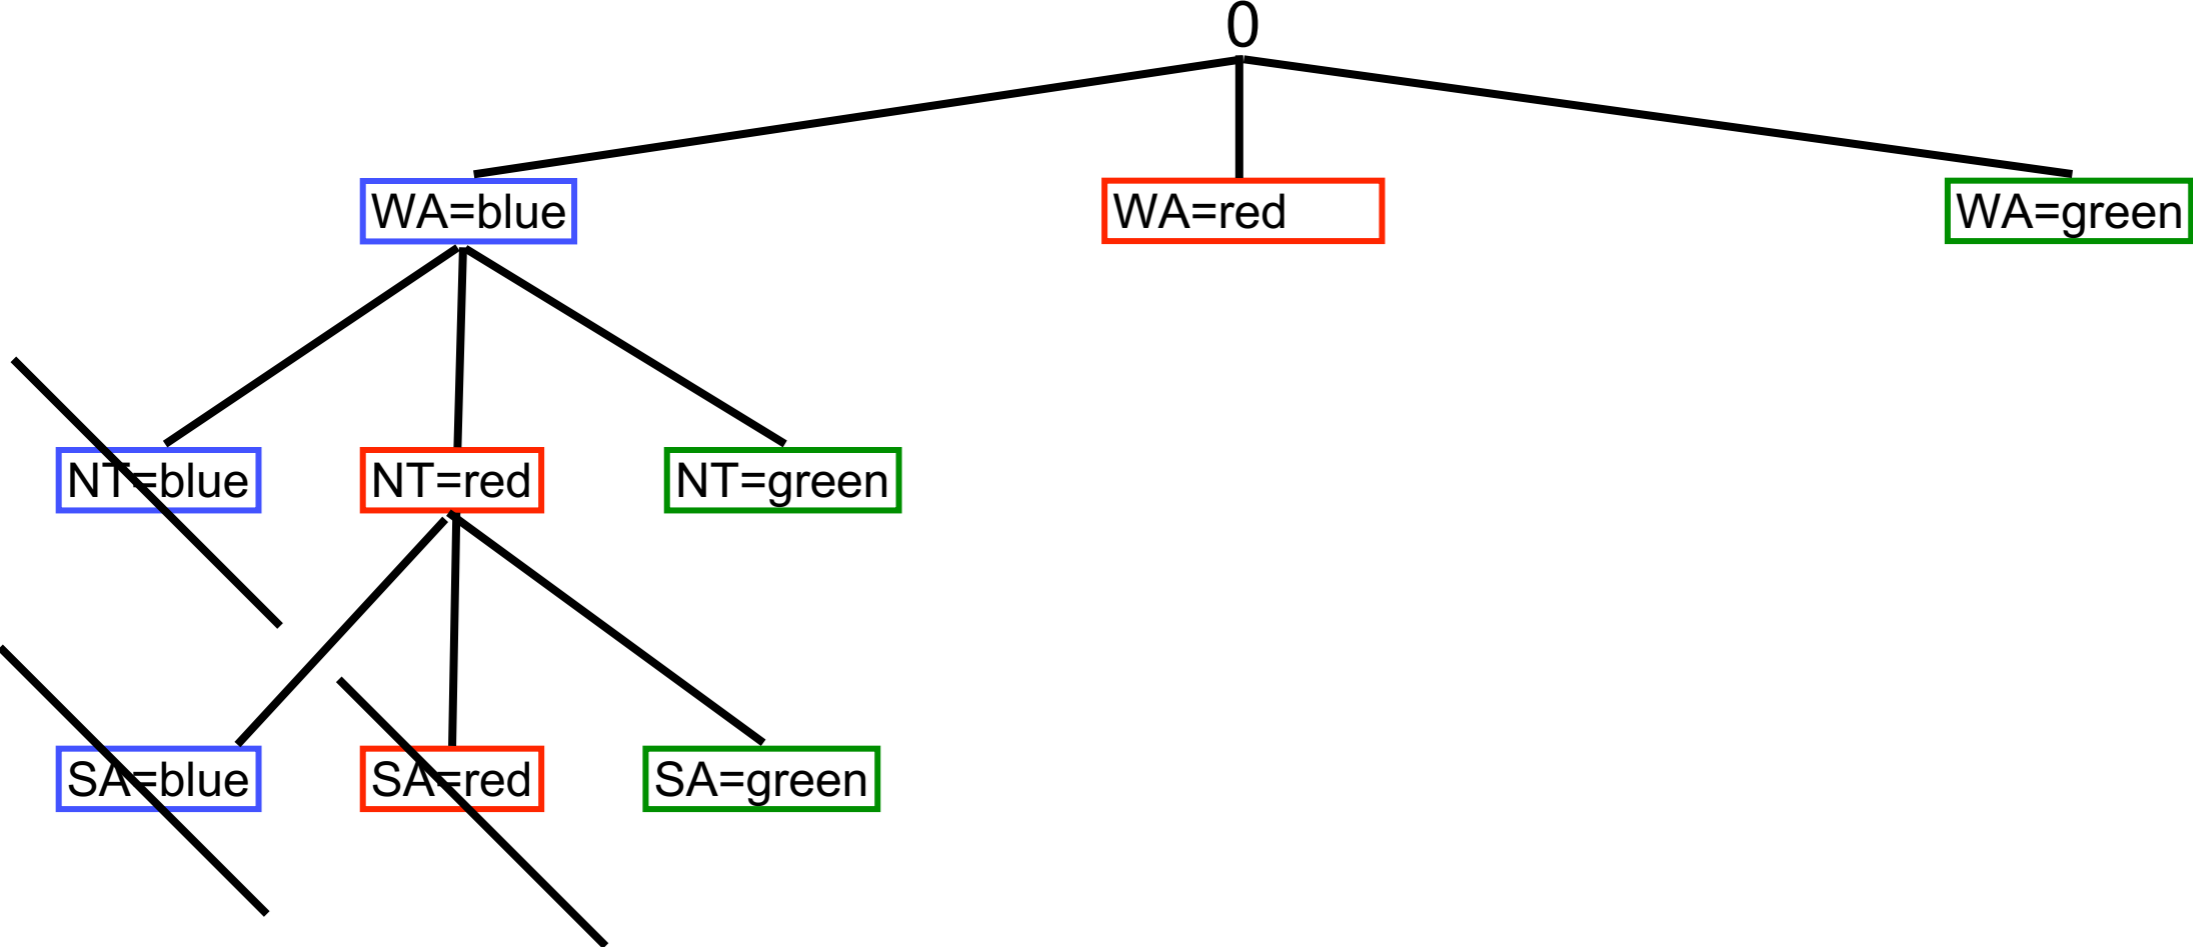

# Backtracking Example

# Backtracking Example

# Backtracking and Efficiency

Note that backtracking search is basically DFS with some small improvements. Can we improve on it further?

## Ordering:

- Which variables should be tried first?
- In what order should a variable's values be tried?

## Filtering:

- Can we detect failure early?

## Structure:

- Can we exploit the problem structure?

# Ordering: Most Constrained Variable

Choose the variable which has the fewest “legal” moves

AKA **minimum remaining values (MRV)**

$D_{NT} = \{\text{green, blue}\}$   
 $D_{SA} = \{\text{green, blue}\}$   
 $D_{\text{others}} = \{\text{red, green, blue}\}$

$D_{SA} = \{\text{blue}\}$   
 $D_Q = \{\text{blue, red}\}$   
 $D_{\text{others}} = \{\text{red, green, blue}\}$

# Ordering: Most Constraining Variable

Most constraining variable:

Choose variable with most constraints on remaining variables

Tie-breaker among most constrained variables

SA is involved in 5 constraints

# Ordering: Least-Constraining Value

Given a variable, choose the least constraining value:

The one that rules out the fewest values in the remaining variables

# Filtering: Forward Checking

Forward checking:

Keep track of remaining legal values for unassigned variables

Terminate search when any variable has no legal values

# Example: Forward Checking

WA	NT	Q	NSW	V	SA	T
RGB	RGB	RGB	RGB	RGB	RGB	RGB

# Example: Forward Checking

WA	NT	Q	NSW	V	SA	T
RGB	RGB	RGB	RGB	RGB	RGB	RGB
R	<del>RGB</del>	RGB	RGB	RGB	<del>RGB</del>	RGB

Forward checking removes the value Red of NT and of SA

# Example: Forward Checking

WA	NT	Q	NSW	V	SA	T
RGB	RGB	RGB	RGB	RGB	RGB	RGB
R	GB	RGB	RGB	RGB	GB	RGB
R	<del>GB</del>	G	<del>RGB</del>	RGB	<del>GB</del>	RGB

# Example: Forward Checking

WA	NT	Q	NSW	V	SA	T
RGB	RGB	RGB	RGB	RGB	RGB	RGB
R	GB	RGB	RGB	RGB	GB	RGB
R	B	G	RB	RGB	B	RGB
R	B	G	<del>RB</del>	B	<del>B</del>	RGB

# Example: Forward Checking

Empty set: the current assignment  
 $\{(WA \leftarrow R), (Q \leftarrow G), (V \leftarrow B)\}$   
does not lead to a solution

WA	NT	Q	NSW	V	SA	T
RGB	RGB	RGB	RGB	RGB	RGB	RGB
R	GB	RGB	RGB	RGB	GB	RGB
R	B	G	RB	RGB	B	RGB
R	B	G	<del>RB</del>	B	<del>B</del>	RGB

# Filtering: Arc Consistency

Forward checking propagates information from assigned to unassigned variables, but it can not detect all future failures early

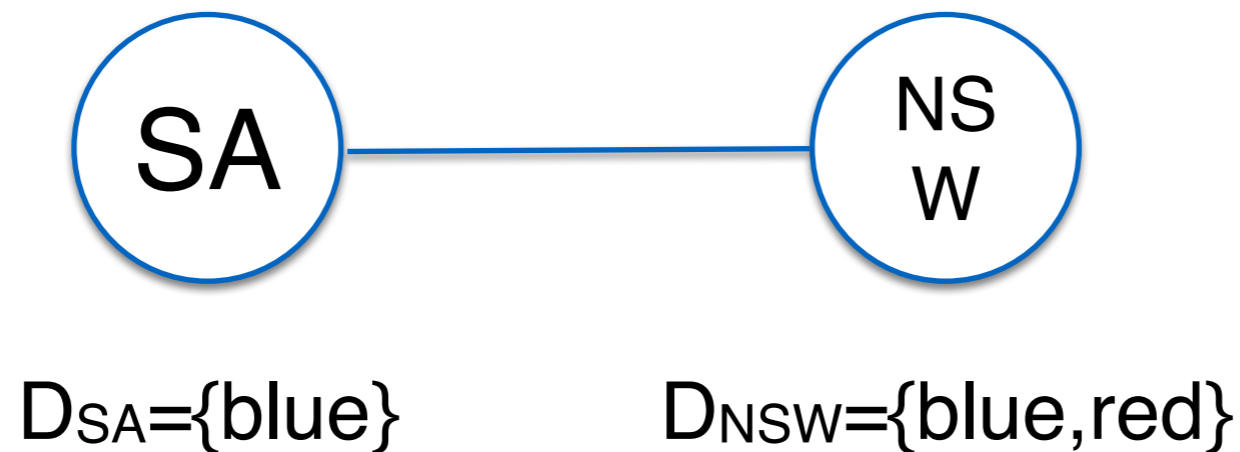

WA	NT	Q	NSW	V	SA	T
RGB	RGB	RGB	RGB	RGB	RGB	RGB
R	GB	RGB	RGB	RGB	GB	RGB
R	B	G	RB	RGB	B	RGB

NT and SA can not both be blue!

Need to reason about constraints

# Filtering: Arc Consistency

Given domains  $D_1$  and  $D_2$ , an arc is consistent if for all  $x$  in  $D_1$  there is a  $y$  in  $D_2$  such that  $x$  and  $y$  are consistent.

Is the arc from SA to NSW consistent?

Is the arc from NSW to SA consistent?

# Structure: Independent Subproblems

Tasmania does not interact with the rest of the problem

**Idea:** Break down the graph into its connected components. Solve each component separately.

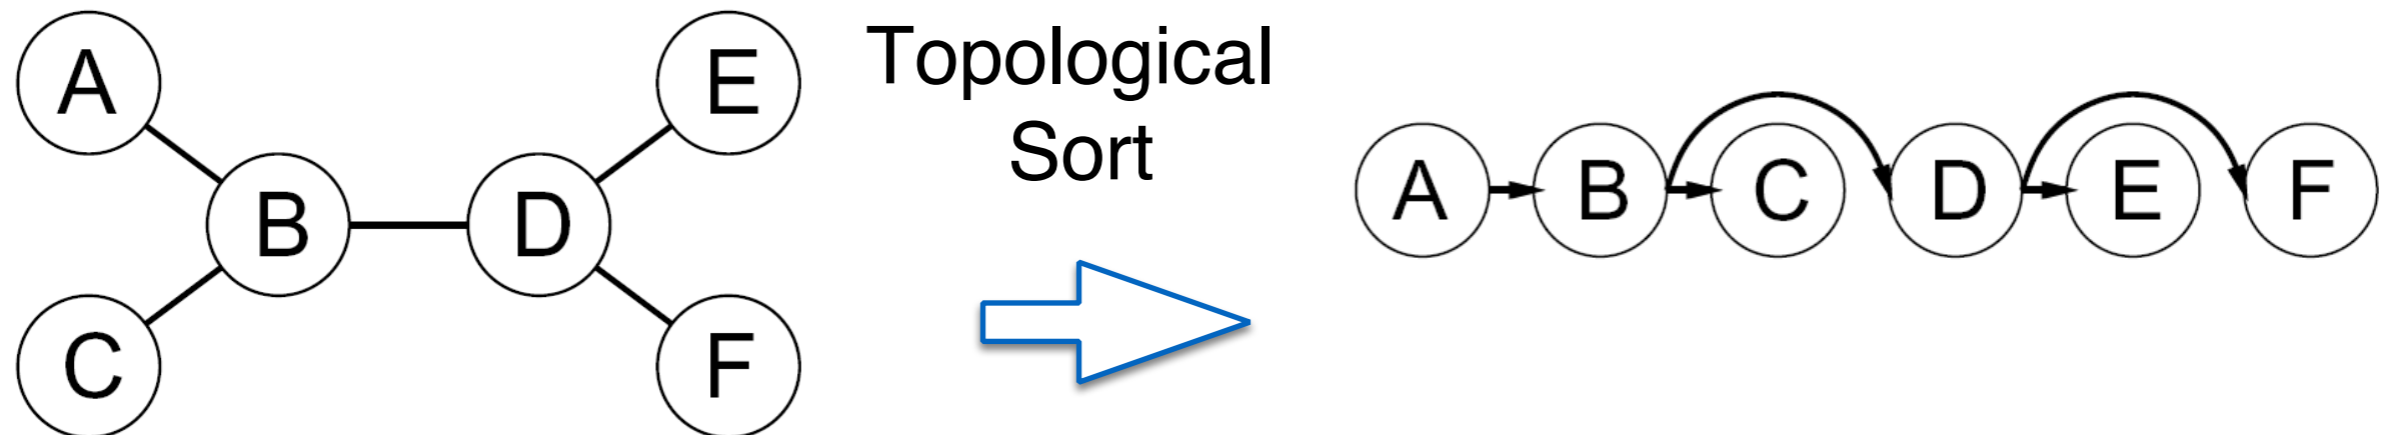

## Significant potential savings:

- Assume  $n$  variables with domain size  $d$ :  $O(d^n)$
- Assume each component involves  $c$  variables ( $n/c$  components) for some constant  $c$ :  $O(d^c n/c)$

# Structure: Tree Structures

CSPs can be solved in  $O(nd^2)$  if there are no loops in the constraint graph

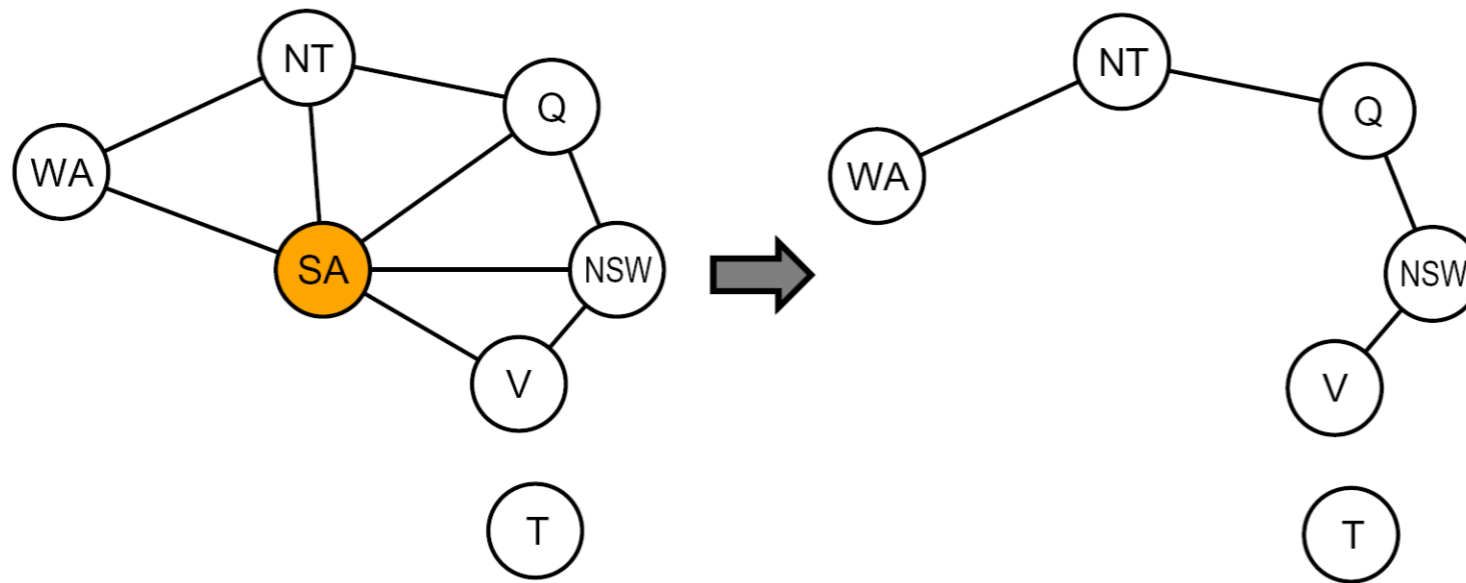

**Step 1:** For  $i=n$  to 1, make-consistent( $X_i$ ,parent( $X_i$ ))

**Step 2:** For  $i=1$  to  $n$ , assign value to  $X_i$  consistent with parent( $X_i$ ) [Note: No backtracking!]

# Structure: Non-Trees?

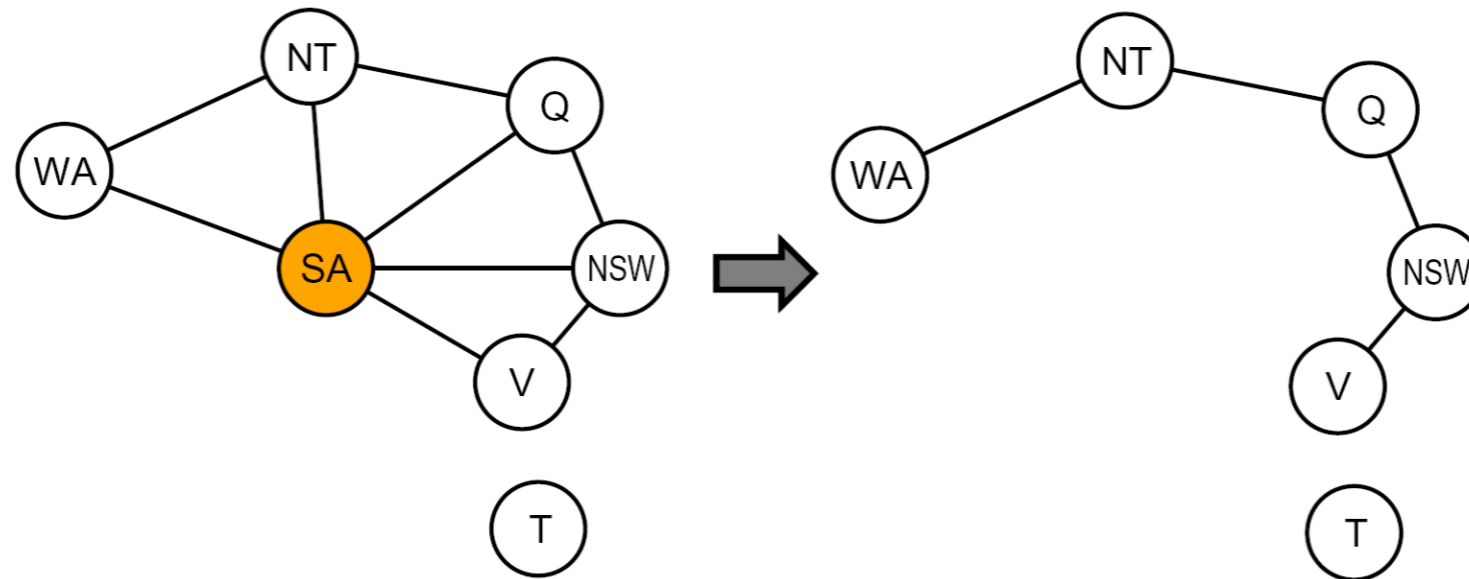

If we assign SA a colour and then remove that colour from the domains all other variables, then we have a tree

**Step 1:** Choose a subset  $S$  of variables such that the constraint graph becomes a tree when  $S$  is removed ( $S$  is the cycle cutset)

**Step 2:** For each possible valid assignment to the variables in  $S$

1. Remove from the domains of remaining variables, all values that are inconsistent with  $S$
2. If the remaining CSP has a solution, return it

# Structure: Cutsets

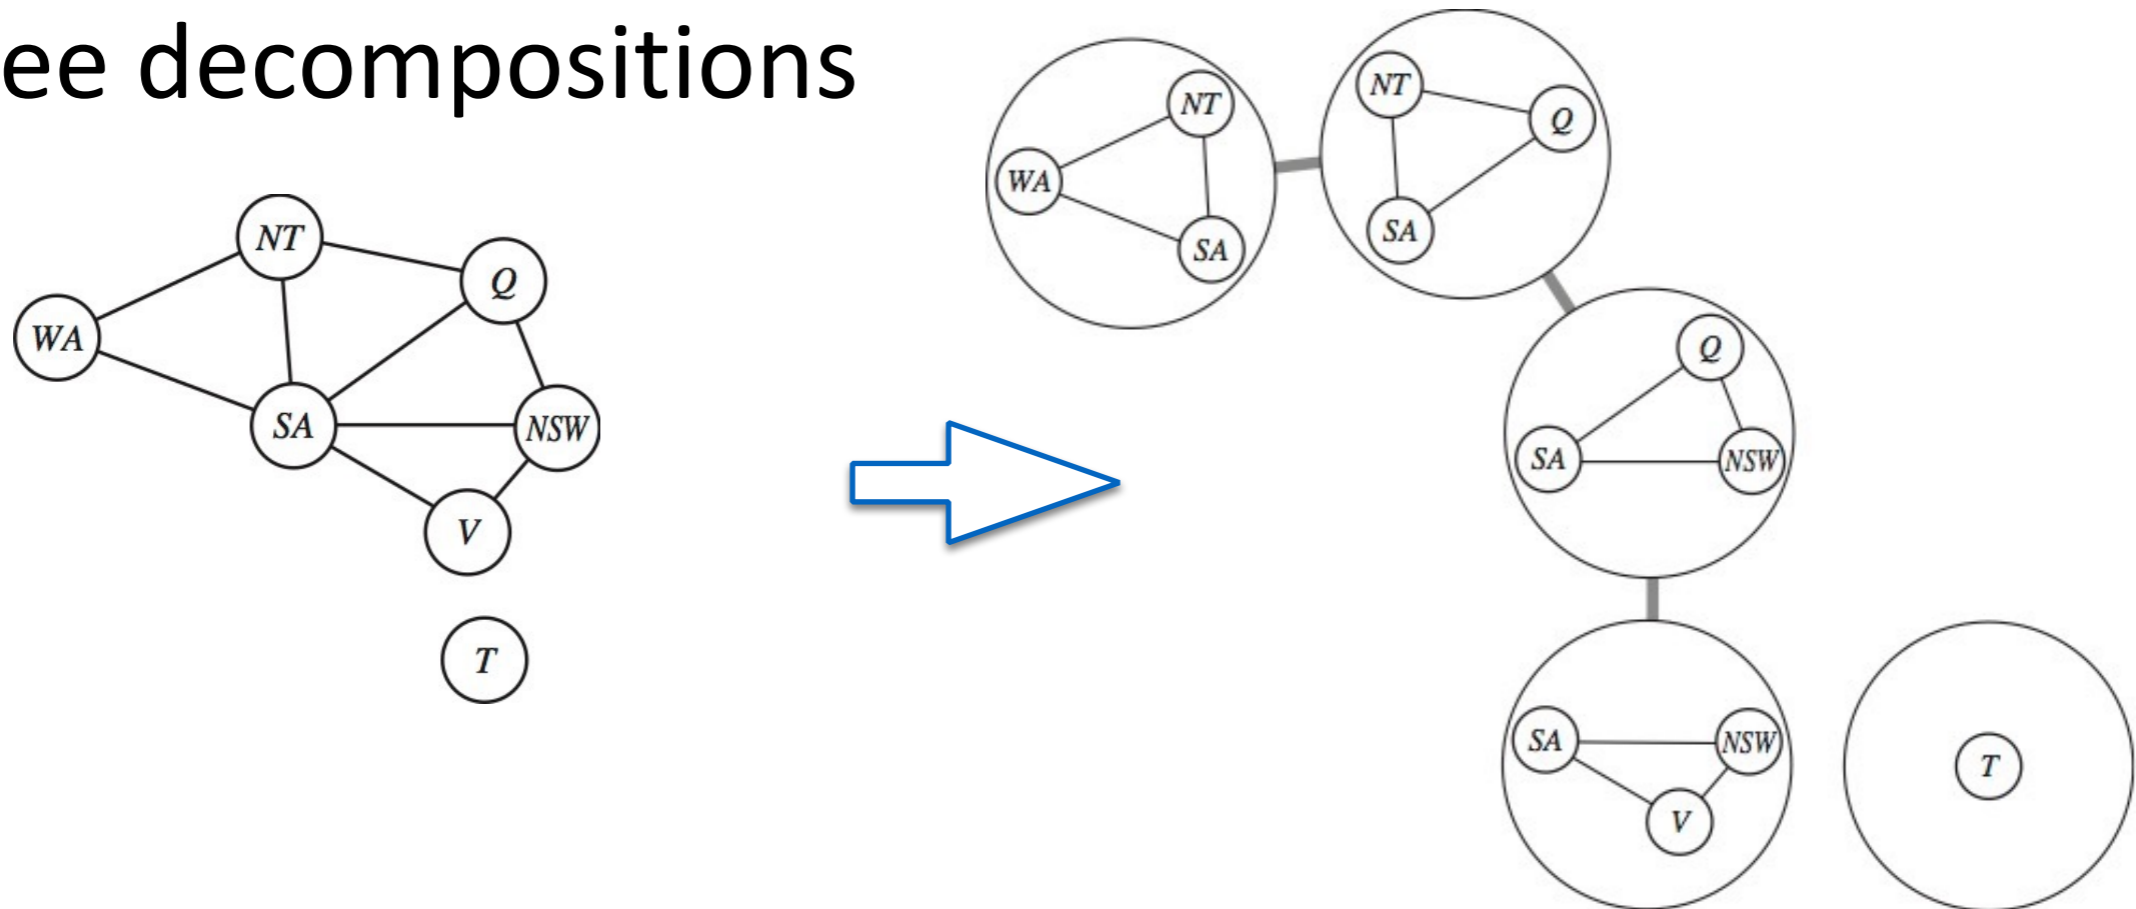

Running time:

- Let  $c$  be the size of the cutset then
  - $d^c$  combinations of variables in  $S$
  - For each combination must solve a tree problem of size  $n-c$  ( $O(n-c)d^2$ )
  - Therefore, running time is  $O(d^c(n-c)d^2)$
- Finding smallest cutset is NP-hard but efficient approximations exist

# Structure: Non-Trees?

## Tree decompositions

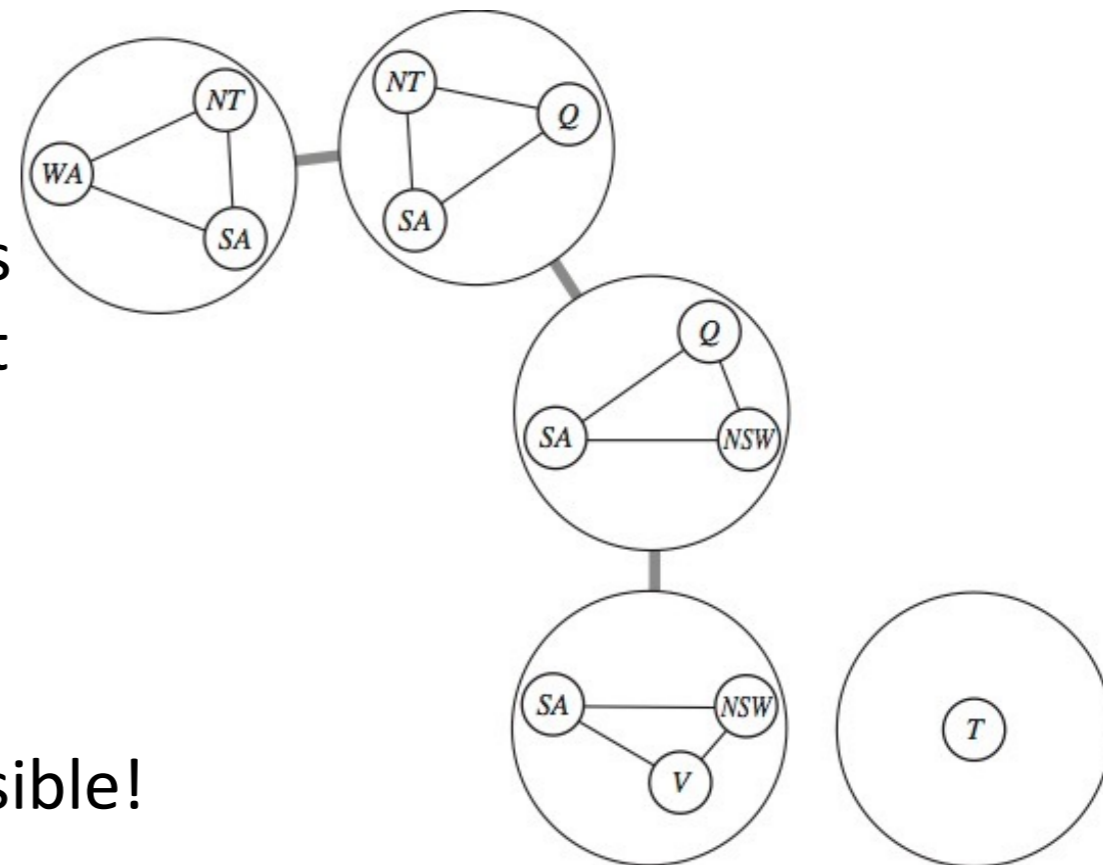

1. Each variable appears in at least one subproblem
2. If two variables are connected by a constraint, then they (and the constraint) must appear together in at least one subproblem
3. If a variable appears in two subproblems in the tree, it must appear in every subproblem along the path connecting those subproblems

# Structure: Tree Decompositions

Solve each subproblem independently

e.g  $\{(WA=r, NT=g, SA=b), (WA=b, NT=g, SA=r), \dots\}$

Solve constraints connecting the subproblems using tree-based algorithm (to make sure that subproblems with shared variables agree)

Want to make the subproblems as small as possible!

Tree width:  $w = \text{Size of largest subproblem} - 1$

Running time  $O(nd^{w+1})$

Finding tree decomposition with min tree-width is NP-hard, but good heuristics exist

# Summary

Formalize problems as CSPs

Backtracking search

Improvements using

- Ordering

- Filtering

- Structure
