The Problem

The Problem: data contention may cause a DBMS to perform poorly if too many transactions run concurrently.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

The Problem

The Problem: data contention may cause a DBMS to perform poorly if too many transactions run concurrently.

The Solution: limit the number of concurrently executing transactions

- What is the actuator?
 - transaction admissions

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ のへぐ

- What is the actuator?
 - transaction admissions
- What is measured?

- What is the actuator?
 - transaction admissions
- What is measured?
 - Control objective is to maximize throughput, avoiding thrashing. Could directly measure throughput.

• Proposal: measure conflict rate, and keep it below a specified target value.

Observation

This turns a dynamic optimization problem into a regulation problem.

Conflict Rate

conflict rate = $\frac{\# \text{ locks held by all transactions}}{\# \text{ locks held by non-blocked transactions}}$

- conflict rate ≥ 1
- conflict rate = 1 when no active transactions are blocked

うつん 川 エー・エー・ エー・シック

conflict rate increases as more transactions block

Conflict Rate

conflict rate = $\frac{\# \text{ locks held by all transactions}}{\# \text{ locks held by non-blocked transactions}}$

- conflict rate ≥ 1
- conflict rate = 1 when no active transactions are blocked
- conflict rate increases as more transactions block

Claim

conflict rate \geq 1.3 implies data-contention thrashing, regardless of the workload

うつん 川 エー・エー・ エー・シック

Regulating Conflict Rate

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで

Proposed Control Rules

- irregular control interval
 - control applied when a lock request blocks and when a transaction request arrives/finishes

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三■ - のへぐ

Proposed Control Rules

- irregular control interval
 - control applied when a lock request blocks and when a transaction request arrives/finishes
- when a transaction arrives/finishes, consider admitting new transactions
 - A0: admit one
 - A1: admit all
 - A2: admit some (until projected conflict rate reaches limit)

Proposed Control Rules

- irregular control interval
 - control applied when a lock request blocks and when a transaction request arrives/finishes
- when a transaction arrives/finishes, consider admitting new transactions
 - A0: admit one
 - A1: admit all
 - A2: admit some (until projected conflict rate reaches limit)
- when transaction blocks, consider aborting transactions
 - C0: abort none
 - C1: abort one
 - C2: abort some (until conflict rate is below limit)

Comments

• 1.3???

Comments

- 1.3???
- In general, there may be multiple potential bottlenecks in the DBMS:

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

- lock contention
- CPU contention
- disk contention

Comments

- 1.3???
- In general, there may be multiple potential bottlenecks in the DBMS:
 - lock contention
 - CPU contention
 - disk contention
- Heiss and Wagner (VLDB'91) attempt to solve the dynamic optimization problem directly
