CS475 / CM375 Lecture 15: Nov 1st, 2011

Rayleigh Quotient Iteration and QR Algorithm Reading: [TB] Chapters 27, 28

CS475/CM375 (c) 2011 P. Poupart & J. Wan

1

Inverse Iteration Algorithm

$$v^{(0)} = \text{some vector with } \left| \left| v^{(0)} \right| \right| = 1$$
 For $k=1,2,...$ Solve $(A-\mu I)w=v^{(k-1)}$
$$v^{(k)}=w/\left| \left| w \right| \right|$$

$$\lambda^{(k)}=\left(v^{(k)}\right)^T A v^{(k)}$$
 end

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Inverse Iteration Algorithm

- Notes
 - 1. If $\mu = \lambda_j$, then $A \mu I$ is singular If $\mu \approx \lambda_j$, then $A \mu I$ is close to being singular It turns out to be OK if the linear system is solved stably
 - 2. Like power iteration, inverse iteration has linear convergence
 - 3. Unlike power iteration, we can choose which eigenvector to compute by choosing μ close to the corresponding λ_i

CS475/CM375 (c) 2011 P. Poupart & J. Wan

3

Inverse Iteration Algorithm

• Theorem: Suppose λ_j is closest to μ and λ_l is the second closest,

i.e.,
$$\left|\mu - \lambda_j\right| < \left|\mu - \lambda_l\right| \le \left|\mu - \lambda_i\right| \ \ \forall i \ne j.$$
 Also suppose $q_j^T v^{(0)} \ne 0$. Then

$$\begin{split} \left| \left| v^{(k)} - \left(\pm q_j \right) \right| \right| &= O\left(\left| \frac{\mu - \lambda_j}{\mu - \lambda_l} \right|^k \right) \\ \text{and } \left| \lambda^{(k)} - \lambda_j \right| &= O\left(\left| \frac{\mu - \lambda_j}{\mu - \lambda_l} \right|^{2k} \right) \quad \text{as } k \to \infty \end{split}$$

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Rayleigh Quotient Iteration

- Rayleigh quotient gives an eigenvalue estimate from an eigenvector estimate
- Inverse iteration gives an eigenvector estimate from an eigenvalue estimate
- Idea: combine the two.

CS475/CM375 (c) 2011 P. Poupart & J. Wan

5

Rayleigh Quotient Iteration Algorithm

$$\begin{split} v^{(0)} &= \text{some vector with } \left| \left| v^{(0)} \right| \right| = 1 \\ \lambda^{(0)} &= \left(v^{(0)} \right)^T A v^{(0)} = r \big(v^{(0)} \big) \\ \text{For } k &= 1, 2, \dots \\ \text{Solve } \big(A - \lambda^{(k-1)} I \big) w = v^{(k-1)} \\ v^{(k)} &= w / ||w|| \\ \lambda^{(k)} &= \left(v^{(k)} \right)^T A v^{(k)} \end{split}$$

end

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Rayleigh Quotient Iteration

• Theorem: RQI converges for most starting vectors $v^{(0)}$. The convergence is cubic:

$$\left| \left| v^{(k+1)} - \left(\pm q_j \right) \right| \right| = O\left(\left| \left| v^{(k)} - \left(\pm q_j \right) \right| \right|^3 \right)$$
$$\left| \lambda^{(k+1)} - \lambda_j \right| = O\left(\left| \lambda^{(k)} - \lambda_j \right|^3 \right)$$

CS475/CM375 (c) 2011 P. Poupart & J. Wan

7

Rayleigh Quotient Iteration

• Proof sketch: Suppose $\left| \left| v^{(k)} - q_j \right| \right| \le \epsilon$. Then $\left| r(v^{(k)}) - r(q_j) \right| = O\left(\left| \left| v^{(k)} - q_j \right| \right| \right)^2$ i.e., $\left| \lambda^{(k)} - \lambda_j \right| = \epsilon^2$. It can be proven that $\left| \left| v^{(k+1)} - q_j \right| \right| = O\left(\left| \lambda^{(k)} - \lambda_j \right| \, \left| \left| v^{(k)} - q_j \right| \right| \right) = O(\epsilon^3)$ Thus $\left| \left| v^{(k)} - q_j \right| \right| \le \epsilon$ $\Rightarrow \left| \lambda^{(k)} - \lambda_j \right| \, \left| \left| v^{(k)} - q_j \right| \right| \le \epsilon^3$ $\Rightarrow \left| \lambda^{(k)} - \lambda_j \right| \, \left| \left| v^{(k)} - q_j \right| \right| \le \epsilon^3$

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Example

• Example of cubic convergence for Rayleigh quotient iteration

$$A = \begin{bmatrix} 2 & 1 & 1 \\ 1 & 3 & 1 \\ 1 & 1 & 4 \end{bmatrix} \quad v^{(0)} = \frac{1}{\sqrt{3}} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

CS475/CM375 (c) 2011 P. Poupart & J. Wan

٥

Second Example

• Comparison of RQI and Power iteration

$$A = \begin{bmatrix} 21 & 7 & -1 \\ 5 & 7 & 7 \\ 4 & -4 & 20 \end{bmatrix} \quad v^{(0)} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Complexity

- Each step of power iteration involves $Av^{(k-1)}$, which takes $O(n^2)$ flops.
- Each step of inverse iteration solves $(A \mu I)^{-1}w = v^{(k-1)}$, which takes $O(n^3)$ flops. One can pre-compute and store L, U factors of $A - \mu I$. Thus each step takes $O(n^2)$ flops for forward and backward solves.
- The matrix $A \lambda^{(k-1)}I$ changes in each step of RQI. Hence it takes $O(n^3)$ flops in general.
- If A is tridiagonal, all 3 methods take O(n) flops per iteration.

CS475/CM375 (c) 2011 P. Poupart & J. Wan

11

Similarity Transformation

- <u>Def:</u> If $X \in \Re^{n \times n}$ is nonsingular, then $A \to X^{-1}AX$ is called a similarity transformation of A.
- <u>Def:</u> A and B are similar if $B = X^{-1}AX$ for some nonsingular X.
- Theorem: If A, B are similar, then they have the same characteristic polynomial and the same eigenvalues
- Proof:

CS475/CM375 (c) 2011 P. Poupart & J. Wan

QR Algorithm

- <u>Idea:</u> Apply a sequence of similarity transformations to *A*, which will converge to a diagonal matrix.
- Consider $A^{(k-1)}$. Compute its QR factorization.

i.e.,
$$R^{(k)} = (Q^{(k)})^T A^{(k-1)}$$

- Then $R^{(k)}Q^{(k)} = \underbrace{(Q^{(k)})^T A^{(k-1)}Q^{(k)}}_{A^{(k)}}$
- Clearly $A^{(k-1)}$ and $A^{(k)}$ are similar

CS475/CM375 (c) 2011 P. Poupart & J. Wan

13

QR Algorithm

$$A^{(0)}=A$$
 For $k=1,2,\dots$
$$Q^{(k)}R^{(k)}=A^{(k-1)} \qquad \text{(QR factorization of } A^{(k-1)}\text{)}$$

$$A^{(k)}=R^{(k)}Q^{(k)}$$

End

How does it work?

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Unnormalized Simultaneous Iteration

- Apply power iteration to several vectors at once and maintain linear independence among the vectors.
- Start with: $v_1^{(0)}, v_2^{(0)}, \dots, v_p^{(0)}$ Then $A^k v_1^{(0)}$ converges to q_1 where $|\lambda_1|$ is largest. Thus span $\{A^k v_1^{(0)}, \dots, A^k v_p^{(0)}\}$ should converge to $\{q_1, \dots, q_p\}$ where $\lambda_1, \dots, \lambda_p$ are the p largest eigenvalues.

CS475/CM375 (c) 2011 P. Poupart & J. Wan

15

Unnormalized Simultaneous Iteration

- Write $V^{(0)} = \begin{bmatrix} v_1^{(0)} & v_2^{(0)} & \dots & v_p^{(0)} \end{bmatrix}$
- $\bullet \ \ \mathsf{Define} \ V^{(k)} \equiv A^k V^{(0)} = \begin{bmatrix} v_1^{(k)} & v_2^{(k)} & \dots & v_p^{(k)} \end{bmatrix}$
- Compute a reduced QR factorization of $V^{(k)}$: $\widehat{Q}^{(k)}\widehat{R}^{(k)} = V^{(k)} \qquad \widehat{Q}^{(k)} \in \Re^{n \times p}, \, \widehat{R}^{(k)} \in \Re^{p \times p}$ As $k \to \infty$, $\widehat{Q}^{(k)}$ should $\to \widehat{Q} \equiv [q_1, \ q_2, \ \dots \ q_p]$

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Unnormalized Simultaneous Iteration

• Assumption 1: the leading p+1 eigenvalues are distinct in absolute values

$$\left|\lambda_{1}\right|>\left|\lambda_{2}\right|>\cdots>\left|\lambda_{p}\right|>\left|\lambda_{p+1}\right|\geq\left|\lambda_{p+2}\right|\geq\cdots\geq\left|\lambda_{n}\right|$$

- Assumption 2: All the leading principal minors of $\widehat{Q}^T V^{(0)}$ are nonsingular
- Theorem: Suppose block power iteration is carried out and assumptions 1 & 2 hold. Then as $k \to \infty$

$$\left| \left| q_j^{(k)} - \left(\pm q_j \right) \right| \right| = O(c^k) \quad j = 1, 2, \dots, p$$
Where $c = \max_{1 \le k \le p} \left| \frac{\lambda_{k+1}}{\lambda_k} \right| < 1$

CS475/CM375 (c) 2011 P. Poupart & J. Wan

17

Unnormalized Simultaneous Iteration

- As $k \to \infty$, the vectors $v_1^{(k)}$, ..., $v_p^{(k)}$ all converge to multiples of the same dominant eigenvector q_1
- <u>Idea:</u> orthogonalize the vectors at each step

CS475/CM375 (c) 2011 P. Poupart & J. Wan

Simultaneous Iteration Algorithm

Pick $\hat{Q}^{(0)} \in \Re^{n \times p}$ with orthonormal columns For k= 1,2, ...

$$Z^{(k)} = A\hat{Q}^{(k-1)}$$
 power iteration

$$\widehat{Q}^{(k)}\widehat{R}^{(k)}=Z^{(k)}$$
 reduced QR factorization

End

Note: The column space of $\hat{Q}^{(k)}$ and $Z^{(k)}$ are the same. They are both equal to that of $A^{(k)}\hat{Q}^{(0)}$.

CS475/CM375 (c) 2011 P. Poupart & J. Wan
