Perceptrons, Neural Networks

[D] Chapt. 4, [HTF] Chapt. 11, [B] Sec.  
4.1.7, 5.1, [M] Sec. 8.5.4, [RN] Sec. 18.7

# Outline

- Neural networks
  - Perceptron
  - Supervised learning algorithms for neural networks

# Brain

- Seat of human intelligence
- Where memory/knowledge resides
- Responsible for thoughts and decisions
- Can learn
- Consists of nerve cells called **neurons**

# Neuron

# Comparison

- Brain
  - Network of neurons
  - Nerve signals propagate in a neural network
  - Parallel computation
  - **Robust (neurons die everyday without any impact)**
- Computer
  - Bunch of gates
  - Electrical signals directed by gates
  - Sequential and parallel computation
  - **Fragile (if a gate stops working, computer crashes)**

# Artificial Neural Networks

- Idea: **mimic the brain to do computation**
- Artificial neural network:
  - Nodes (a.k.a. units) correspond to neurons
  - Links correspond to synapses
- Computation:
  - Numerical signal transmitted between nodes corresponds to chemical signals between neurons
  - Nodes modifying numerical signal corresponds to neurons firing rate

# ANN Unit

- For each unit  $i$ :
- **Weights:  $W$** 
  - Strength of the link from unit  $i$  to unit  $j$
  - Input signals  $x_i$  weighted by  $W_{ji}$  and linearly combined:  
$$a_j = \sum_i W_{ji} x_i + w_0 = \mathbf{W}_j \bar{\mathbf{x}}$$
- **Activation function:  $h$** 
  - Numerical signal produced:  $y_j = h(a_j)$

# ANN Unit

- Picture

# Activation Function

- Should be nonlinear
  - Otherwise network is just a linear function
- Often chosen to mimic firing in neurons
  - Unit should be “active” (output near 1) when fed with the “right” inputs
  - Unit should be “inactive” (output near 0) when fed with the “wrong” inputs

# Common Activation Functions

Threshold

Sigmoid

# Logic Gates

- McCulloch and Pitts (1943)
  - Design ANNs to represent Boolean functions
- What should be the weights of the following units to code AND, OR, NOT ?

**AND**

**OR**

**NOT**

# Network Structures

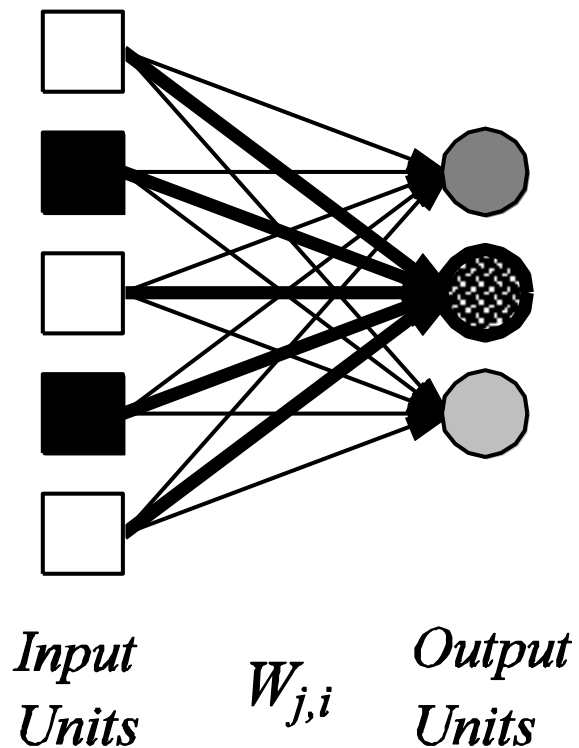

- **Feed-forward network**
  - Directed **acyclic** graph
  - No internal state
  - Simply computes outputs from inputs
  
- **Recurrent network**
  - Directed **cyclic** graph
  - Dynamical system with internal states
  - Can memorize information

# Feed-forward network

- Simple network with two inputs, one hidden layer of two units, one output unit

# Perceptron

- Single layer feed-forward network

# Supervised Learning

- Given list of  $(\mathbf{x}, \mathbf{y})$  pairs
- Train feed-forward ANN
  - To compute proper outputs  $\mathbf{y}$  when fed with inputs  $\mathbf{x}$
  - Consists of adjusting weights  $W_{ji}$
- **Simple learning algorithm for threshold perceptrons**

# Threshold Perceptron Learning

- Learning is done separately for each unit  $j$ 
  - Since units do not share weights
- Perceptron learning for unit  $j$ :
  - For each  $(\mathbf{x}, y)$  pair do:
    - Case 1: correct output produced
$$\forall_i W_{ji} \leftarrow W_{ji}$$
    - Case 2: output produced is 0 instead of 1
$$\forall_i W_{ji} \leftarrow W_{ji} + x_i$$
    - Case 3: output produced is 1 instead of 0
$$\forall_i W_{ji} \leftarrow W_{ji} - x_i$$
  - Until correct output for all training instances

# Threshold Perceptron Learning

- Dot products:  $\bar{\mathbf{x}}^T \bar{\mathbf{x}} \geq 0$  and  $-\bar{\mathbf{x}}^T \bar{\mathbf{x}} \leq 0$
- Perceptron computes
  - 1 when  $\mathbf{w}^T \bar{\mathbf{x}} = \sum_i x_i w_i + w_0 > 0$
  - 0 when  $\mathbf{w}^T \bar{\mathbf{x}} = \sum_i x_i w_i + w_0 < 0$
- If output should be 1 instead of 0 then
  - $\mathbf{w} \leftarrow \mathbf{w} + \bar{\mathbf{x}}$  since  $(\mathbf{w} + \bar{\mathbf{x}})^T \bar{\mathbf{x}} \geq \mathbf{w}^T \bar{\mathbf{x}}$
- If output should be 0 instead of 1 then
  - $\mathbf{w} \leftarrow \mathbf{w} - \bar{\mathbf{x}}$  since  $(\mathbf{w} - \bar{\mathbf{x}})^T \bar{\mathbf{x}} \leq \mathbf{w}^T \bar{\mathbf{x}}$

# Alternative Approach

- Let  $y \in \{-1, 1\} \forall y$
- Let  $M = \{(\mathbf{x}_n, y_n)_{\forall n}\}$  be set of misclassified examples
  - i.e.,  $y_n \mathbf{w}^T \bar{\mathbf{x}}_n < 0$

- Find  $\mathbf{w}$  that minimizes misclassification error

$$E(\mathbf{w}) = - \sum_{(\mathbf{x}_n, y_n) \in M} y_n \mathbf{w}^T \bar{\mathbf{x}}_n$$

- Algorithm: gradient descent

$$\mathbf{w} \leftarrow \mathbf{w} - \eta \nabla E$$

↘ learning rate  
or step length

# Sequential Gradient Descent

- Gradient:  $\nabla E = - \sum_{(x_n, y_n) \in M} y_n \bar{\mathbf{x}}_n$
- Sequential gradient descent:
  - Adjust  $\mathbf{w}$  based on one example  $(\mathbf{x}, y)$  at a time
$$\mathbf{w} \leftarrow \mathbf{w} + \eta y \bar{\mathbf{x}}$$
- When  $\eta = 1$ , we recover the threshold perceptron learning algorithm

# Threshold Perceptron Hypothesis Space

- Hypothesis space  $h_{\mathbf{w}}$ :
  - All binary classifications with parameters  $\mathbf{w}$  s.t.
    - $\mathbf{w}^T \bar{\mathbf{x}} > 0 \rightarrow +1$
    - $\mathbf{w}^T \bar{\mathbf{x}} < 0 \rightarrow -1$
- Since  $\mathbf{w}^T \bar{\mathbf{x}}$  is linear in  $\mathbf{w}$ , perceptron is called a **linear separator**
- **Theorem:** Threshold perceptron learning converges iff the data is linearly separable

# Linear Separability

- Examples:

Linearly separable

Non-linearly separable

# Sigmoid Perceptron

- Represent “soft” linear separators
- **Same hypothesis space as logistic regression**

# Sigmoid Perceptron Learning

- Possible objectives
  - **Minimum squared error**

$$E(\mathbf{w}) = \frac{1}{2} \sum_n E_n(\mathbf{w})^2 = \frac{1}{2} \sum_n \left( y_n - \sigma(\mathbf{w}^T \bar{\mathbf{x}}_n) \right)^2$$

- **Maximum likelihood**
  - Same algorithm as for logistic regression
- Maximum a posteriori hypothesis
- Bayesian Learning

# Gradient

- Gradient:

$$\begin{aligned}\frac{\partial E}{\partial w_i} &= \sum_n E_n(w) \frac{\partial E_n}{\partial w_i} \\ &= -\sum_n E_n(w) \sigma'(w^T \bar{x}_n) x_i\end{aligned}$$

Recall that  $\sigma' = \sigma(1 - \sigma)$

$$= -\sum_n E_n(w) \sigma(w^T \bar{x}_n) (1 - \sigma(w^T \bar{x}_n)) x_i$$

# Sequential Gradient Descent

- Perceptron-Learning(examples, network)
  - Repeat
    - For each  $(\mathbf{x}_n, y_n)$  in examples do
$$E_n \leftarrow y_n - \sigma(\mathbf{w}^T \bar{\mathbf{x}}_n)$$
$$\mathbf{w} \leftarrow \mathbf{w} + \eta E_n \sigma(\mathbf{w}^T \bar{\mathbf{x}}_n) (1 - \sigma(\mathbf{w}^T \bar{\mathbf{x}}_n)) \bar{\mathbf{x}}_n$$
  - Until some stopping criterion satisfied
  - Return learnt network
- N.B.  $\eta$  is a learning rate corresponding to the step size in gradient descent

# Multilayer Networks

- Adding two sigmoid units with parallel but opposite “cliffs” produces a ridge

# Multilayer Networks

- Adding two intersecting ridges (and thresholding) produces a bump

Network output

# Multilayer Networks

- By tiling bumps of various heights together, we can approximate any function
- Training algorithm:
  - **Back-propagation**
  - Essentially sequential gradient descent performed by propagating errors backward into the network
  - Derivation next class

# Neural Net Applications

- Neural nets can approximate any function, hence millions of applications
  - Speech recognition
  - Word embeddings
  - Machine translation
  - Vision-based object recognition
  - Vision-based autonomous driving
  - Etc.
