# CS485/685 Lecture 16: March 3, 2016

Support Vector Machines (continued) [B] Sec. 7.1 [D] Sec. 6.7 [HTF] Chap. 12

[M] Sec. 14.5 [RN] 18.9 [MRT] Chap. 4

### Overlapping Class Distributions

- So far we assumed that data is linearly separable
  - High dimensions help for linear separability, but may hurt for generalization
- But what if the data is noisy (mistakes or outliers)
  - Constraints should allow misclassifications
- Picture

### Soft margin

• Idea: relax constraints by introducing slack variables  $\xi_n \geq 0$ 

$$y_n \mathbf{w}^T \phi(\mathbf{x}_n) \ge 1 - \xi_n \quad \forall n$$

• Picture:

### Soft margin classifier

New optimization problem:

$$\min_{\boldsymbol{w},\boldsymbol{\xi}} C \sum_{n=1}^{N} \xi_n + \frac{1}{2} ||\boldsymbol{w}||^2$$
 s.t.  $y_n \, \boldsymbol{w}^T \phi(\boldsymbol{x}_n) \ge 1 - \xi_n$  and  $\xi_n \ge 0 \quad \forall n$ 

• where C > 0 controls the trade-off between the slack variable penalty and the margin

## Soft margin classifier

#### Notes:

- 1. Since  $\sum_n \xi_n$  is an upper bound on the # of misclassifications, C can also be thought as a regularization coefficient that controls the trade-off between error minimization and model complexity
- 2. When  $C \rightarrow \infty$ , then we recover the original hard margin classifier
- 3. Soft margins handle minor misclassifications, but the classifier is still very sensitive to outliers

### **Support Vectors**

As before support vectors correspond to active constraints

$$y_n \mathbf{w}^T \phi(\mathbf{x}_n) = 1 - \xi_n$$

- i.e., all points that are in the margin or misclassified
- Picture:

### Multiclass SVMs

#### Three methods:

- 1. One-against-all: for K classes, train K SVMs to distinguish each class from the rest
- 2. Pairwise comparison: train  $O(K^2)$  SVMs to compare each pair of classes
- 3. Continuous ranking: single SVM that returns a continuous value to rank all classes

### One-Against-All

- For K classes, train K SVMs to distinguish each class from the rest
- Picture:

 Problem: what if different classes are returned by different SVMs?

### Pairwise Comparison

- Train  $O(K^2)$  SVMs to compare each pair of classes
- Picture:

Problem: how do we pick the best class?

### Continuous Ranking

- Single SVM that returns a continuous value to rank all classes
- Picture:

Most popular approach today

## Continuous Ranking

• Idea: instead of computing the sign of a linear separator, compare the values of linear functions for each class k

Classification:

$$y_* = argmax_k \mathbf{w}_k^T \phi(\mathbf{x}_*)$$

### Multiclass Margin

• For each class  $k \neq y$  define a linear constraint:

$$\mathbf{w}_{v}^{T}\phi(\mathbf{x}) - \mathbf{w}_{k}^{T}\phi(\mathbf{x}) \ge 1 \quad \forall k \ne y$$

This guarantees a margin of at least 1

### Multiclass Classification

Optimization problem:

$$\min_{\boldsymbol{W}} \frac{1}{2} \sum_{k} ||\boldsymbol{w}_{k}||^{2}$$
  
s.t.  $\boldsymbol{w}_{y_{n}}^{T} \phi(\boldsymbol{x}_{n}) - \boldsymbol{w}_{k}^{T} \phi(\boldsymbol{x}) \geq 1 \quad \forall n, k \neq y_{n}$ 

Equivalent to binary SVM when we have only two classes

### Overlapping classes

Add slack variables:

$$\min_{\boldsymbol{W},\boldsymbol{\xi}} C \sum_{n} \xi_{n} + \frac{1}{2} \sum_{k} ||\boldsymbol{w}_{k}||^{2}$$
s.t.  $\boldsymbol{w}_{y_{n}}^{T} \phi(\boldsymbol{x}_{n}) - \boldsymbol{w}_{r}^{T} \phi(\boldsymbol{x}) \geq 1 - \xi_{n} \ \forall n, k \neq y_{k}$ 

Equivalent to binary SVM when we have only two classes
