CS885 Reinforcement Learning Module 2: June 6, 2020

Maximum Entropy Reinforcement Learning

Haarnoja, Tang et al. (2017) Reinforcement Learning with Deep Energy Based Policies, *ICML*.

Haarnoja, Zhou et al. (2018) Soft Actor-Critic: Off-Policy Maximum Entropy Deep Reinforcement Learning with a Stochastic Actor, *ICML*.

Maximum Entropy RL

 Why do several implementations of important RL baselines (e.g., A2C, PPO) add an entropy regularizer?

Why is maximizing entropy desirable in RL?

What is the Soft Actor Critic algorithm?

Reinforcement Learning

Deterministic Policies

- There always exists an optimal deterministic policy
- Search space is smaller for deterministic than stochastic policies
- Practitioners prefer deterministic policies

Stochastic Policies

- Search space is continuous for stochastic policies (helps with gradient descent)
- More robust (less likely to overfit)
- Naturally incorporate exploration
- Facilitate transfer learning
- Mitigate local optima

Encouraging Stochasticity

Standard MDP

States: S

Actions: A

• Reward: R(s,a)

• Transition: Pr(s'|s,a)

• Discount: γ

Soft MDP

• States: S

• Actions: A

• Reward: $R(s,a) + \lambda H(\pi(\cdot | s))$

• Transition: Pr(s'|s,a)

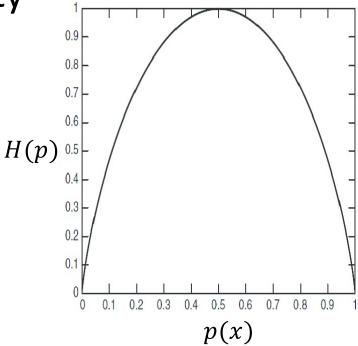

• Discount: γ

Entropy

- Entropy: measure of uncertainty
 - Information theory: expected #
 of bits needed to communicate
 the result of a sample

$$H(p) = -\sum_{x} p(x) \log p(x)$$

Optimal Policy

Standard MDP

$$\pi^* = \underset{\pi}{\operatorname{argmax}} \sum_{n=0}^{N} \gamma^n E_{s_n, a_n \mid \pi} [R(s_n, a_n)]$$

Soft MDP

$$\pi_{soft}^* = \underset{\pi}{\operatorname{argmax}} \sum_{n=0}^{N} \gamma^n E_{s_n, a_n \mid \pi} \left[R(s_n, a_n) + \lambda H(\pi(\cdot \mid s_n)) \right]$$

Maximum entropy policy Entropy regularized policy

Q-function

Standard MDP

$$Q^{\pi}(s_0, a_0) = R(s_0, a_0) + \sum_{n=1}^{\infty} \gamma^n E_{s_n, a_n \mid s_0, a_0, \pi} [R(s_n, a_n)]$$

Soft MDP

$$Q_{soft}^{\pi}(s_0, a_0) = R(s_0, a_0) + \sum_{n=1}^{\infty} \gamma^n E_{s_n, a_n \mid s_0, a_0, \pi} \left[R(s_n, a_n) + \lambda H(\pi(\cdot \mid s_n)) \right]$$

NB: No entropy with first reward term since action is not chosen according to π

Greedy Policy

Standard MDP (deterministic policy)

$$\pi_{greedy}(s) = \underset{a}{\operatorname{argmax}} Q(s, a)$$

Soft MDP (stochastic policy)

$$\pi_{greedy}(\cdot | s) = \underset{\pi}{\operatorname{argmax}} \sum_{a} \pi(a|s) Q(s, a) + \lambda H(\pi(\cdot | s))$$

$$= \frac{\exp(Q(s, \cdot)/\lambda)}{\sum_{a} \exp(Q(s, a)/\lambda)} = \operatorname{softmax}(Q(s, \cdot)/\lambda)$$

when $\lambda \to 0$ then softmax becomes regular max

Derivation

Concave objective (can find global maximum)

$$J(\pi, Q) = \sum_{a} \pi(a|s)Q(s, a) + \lambda H(\pi(\cdot|s))$$

= $\sum_{a} \pi(a|s)[Q(s, a) - \lambda \log \pi(a|s)]$

Partial derivative

$$\frac{\partial J}{\partial \pi(a|s)} = Q(s,a) - \lambda[\log \pi(a|s) + 1]$$

- Setting the derivative to 0 and isolating $\pi(a|s)$ yields $\pi(a|s) = \exp(Q(s,a)/\lambda 1) \propto \exp(Q(s,a)/\lambda)$
- Hence $\pi_{greedy}(\cdot | s) = \frac{\exp(Q(s, \cdot)/\lambda)}{\sum_{a} \exp(Q(s, a)/\lambda)} = softmax(Q(s, \cdot)/\lambda)$

Greedy Value function

What is the value function induced by the greedy policy?

• Standard MDP:
$$V(s) = \max_{a} Q(s, a)$$

Soft MDP:

$$V_{soft}(s) = \lambda H\left(\pi_{greedy}(\cdot | s)\right) + \sum_{a} \pi_{greedy}(a | s) Q_{soft}(s, a)$$
$$= \lambda \log \sum_{a} \exp\left(\frac{Q_{soft}(s, a)}{\lambda}\right) = \widetilde{max}_{\lambda} Q_{soft}(s, a)$$

when $\lambda \to 0$ then $\widetilde{max}_{\lambda}$ becomes regular max

Derivation

$$\begin{split} V_{soft}(s) \\ &= \lambda H\left(\pi_{greedy}(\cdot \mid s)\right) + \sum_{a} \pi_{greedy}(a \mid s) Q_{soft}(s, a) \\ &= \inf\left(\pi_{greedy}(a \mid s)\right) = \frac{\exp\left(Q_{soft}(s, a) / \lambda\right)}{\sum_{a'} \exp\left(Q_{soft}(s, a') / \lambda\right)} \\ &= \lambda H\left(\pi_{greedy}(\cdot \mid s)\right) + \sum_{a} \pi_{greedy}(a \mid s) \lambda \left[\log \pi_{greedy}(a \mid s) + \log \sum_{a'} \exp\left(\frac{Q_{soft}(s, a')}{\lambda}\right)\right] \\ &= \lambda H\left(\pi_{greedy}(\cdot \mid s)\right) + \lambda \sum_{a} \pi_{greedy}(a \mid s) \log \pi_{greedy}(a \mid s) + \lambda \log \sum_{a'} \exp\left(\frac{Q_{soft}(s, a')}{\lambda}\right) \\ &= \lambda H\left(\pi_{greedy}(\cdot \mid s)\right) - \lambda H\left(\pi_{greedy}(\cdot \mid s)\right) + \lambda \log \sum_{a'} \exp\left(\frac{Q_{soft}(s, a')}{\lambda}\right) \\ &= \lambda \log \sum_{a'} \exp\left(\frac{Q_{soft}(s, a')}{\lambda}\right) \\ &= \max_{a} \lambda Q_{soft}(s, a) \end{split}$$

Soft Q-Value Iteration

```
SoftQValueIteration(MDP, \lambda)
Initialize \pi_0 to any policy
i \leftarrow 0
Repeat
Q_{soft}^{i+1}(s,a) \leftarrow R(s,a) + \gamma \sum_{s'} \Pr(s'|s,a) \max_{a'} Q_{soft}^{i}(s',a')
i \leftarrow i+1
Until \left|\left|Q_{soft}^{i}(s,a) - Q_{soft}^{i-1}(s,a)\right|\right|_{\infty} \leq \epsilon
Extract policy: \pi_{greedy}(\cdot |s) = softmax(Q_{soft}^{i}(s,\cdot)/\lambda)
```

Soft Bellman equation:

$$Q_{soft}^*(s,a) = R(s,a) + \gamma \sum_{s'} \Pr(s'|s,a) \max_{a'} Q_{soft}^*(s',a')$$

Soft Q-learning

- Q-learning based on Soft Q-Value Iteration
- Replace expectations by samples
- Represent Q-function by a function approximator (e.g., neural network)
- Do gradient updates based on temporal differences

Soft Q-learning (soft variant of DQN)

Initialize weights w and \overline{w} at random in [-1,1]

Observe current state s

Loop

Select action a and execute it

Receive immediate reward *r*

Observe new state s'

Add (s, a, s', r) to experience buffer

Sample mini-batch of experiences from buffer

For each experience $(\hat{s}, \hat{a}, \hat{s}', \hat{r})$ in mini-batch

Gradient:
$$\frac{\partial Err}{\partial w} = \left[Q_w^{soft}(\hat{s}, \hat{a}) - \hat{r} - \gamma \max_{\hat{a}'} Q_{\overline{w}}^{soft}(\hat{s}', \hat{a}') \right] \frac{\partial Q_w^{soft}(\hat{s}, \hat{a})}{\partial w}$$

Update weights: $\mathbf{w} \leftarrow \mathbf{w} - \alpha \frac{\partial Err}{\partial \mathbf{w}}$

Update state: $s \leftarrow s'$

Every c steps, update target: $\overline{\boldsymbol{w}} \leftarrow \boldsymbol{w}$

Soft Actor Critic

- In practice, actor critic techniques tend to perform better than Q-learning.
- Can we derive a soft actor-critic algorithm?

- Yes, idea:
 - Critic: soft Q-function
 - Actor: (greedy) softmax policy

Soft Policy Iteration

```
SoftPolicyIteration(MDP, \lambda)
     Initialize \pi_0 to any policy
     i \leftarrow 0
     Repeat
         Policy evaluation:
          Repeat until convergence
              Q_{soft}^{\pi_i}(s,a) \leftarrow R(s,a)
                     +\gamma \sum_{s'} \Pr(s'|s,a) \left[ \sum_{a'} \pi_i(a'|s') Q_{soft}^{\pi_i}(s',a') + \lambda H(\pi_i(\cdot|s')) \right] \forall s,a
         Policy improvement:
         \pi_{i+1}(a|s) \leftarrow softmax\left(Q_{soft}^{\pi_i}(s,a)/\lambda\right) = \frac{\exp\left(Q_{soft}^{\pi_i}(s,a)/\lambda\right)}{\sum_{s} \exp\left(Q_{soft}^{\pi_i}(s,a)/\lambda\right)} \ \forall s,a
         i \leftarrow i + 1
    Until \left| \left| Q_{soft}^{\pi_i}(s, a) - Q_{soft}^{\pi_{i-1}}(s, a) \right| \right| \le \epsilon
```

Policy improvement

Theorem 1: Let
$$Q_{soft}^{\pi_i}(s,a)$$
 be the Q-function of π_i Let $\pi_{i+1}(a|s) = softmax\left(Q_{soft}^{\pi_i}(s,a)/\lambda\right)$ Then $Q_{soft}^{\pi_{i+1}}(s,a) \geq Q_{soft}^{\pi_i}(s,a) \ \forall s,a$

Proof: first show that

$$\sum_{a} \pi_{i}(a|s) Q_{soft}^{\pi_{i}}(s,a) + \lambda H(\pi_{i}(\cdot|s))$$

$$\leq \sum_{a} \pi_{i+1}(a|s) Q_{soft}^{\pi_{i}}(s,a) + \lambda H(\pi_{i+1}(\cdot|s))$$

then use this inequality to show that

$$Q_{soft}^{\pi_{i+1}}(s,a) \ge Q_{soft}^{\pi_i}(s,a) \ \forall s,a$$

Inequality derivation

$$\begin{split} & \sum_{a} \pi_{i}(a|s) Q_{soft}^{\pi_{i}}(s,a) + \lambda H \big(\pi_{i}(\cdot|s) \big) \\ & = \sum_{a} \pi_{i}(a|s) \left[Q_{soft}^{\pi_{i}}(s,a) - \lambda \log \pi_{i}(a|s) \right] \\ & \quad \text{since } \pi_{i+1}(a|s) = \frac{\exp\left(Q_{soft}^{\pi_{i}}(s,a)/\lambda\right)}{\sum_{a'} \exp\left(Q_{soft}^{\pi_{i}}(s,a')/\lambda\right)} \\ & = \sum_{a} \pi_{i}(a|s) \left[\lambda \log \pi_{i+1}(a|s) + \lambda \log \sum_{a'} \exp\left(Q_{soft}^{\pi_{i}}(s,a')/\lambda\right) - \lambda \log \pi_{i}(a|s) \right] \\ & = \lambda \sum_{a} \pi_{i}(a|s) \left[\log \frac{\pi_{i+1}(a|s)}{\pi_{i}(a|s)} + \log \sum_{a'} \exp\left(Q_{soft}^{\pi_{i}}(s,a')/\lambda\right) \right] \\ & = -\lambda K L(\pi_{i+1}||\pi_{i}) + \lambda \sum_{a} \pi_{i}(a|s) \log \sum_{a'} \exp\left(Q_{soft}^{\pi_{i}}(s,a')/\lambda\right) \\ & \leq \lambda \sum_{a} \pi_{i}(a|s) \log \sum_{a'} \exp\left(Q_{soft}^{\pi_{i}}(s,a')/\lambda\right) \\ & \leq \lambda \sum_{a} \pi_{i}(a|s) \log \sum_{a'} \exp\left(Q_{soft}^{\pi_{i}}(s,a')/\lambda\right) \\ & = \sum_{a} \pi_{i+1}(a|s) \lambda \log \sum_{a'} \exp\left(Q_{soft}^{\pi_{i}}(s,a')/\lambda\right) \\ & = \sum_{a} \pi_{i+1}(a|s) \left[Q_{soft}^{\pi_{i}}(s,a) - \lambda \log \pi_{i+1}(s,a)\right] \\ & = \sum_{a} \pi_{i+1}(a|s) Q_{soft}^{\pi_{i}}(s,a) + \lambda H \big(\pi_{i+1}(\cdot|s)\big) \end{split}$$

Proof derivation

$$\begin{split} Q_{soft}^{\pi_i}(s,a) &= R(s,a) + \gamma E_{s'} \left[E_{a' \sim \pi_i} \left[Q_{soft}^{\pi_i}(s',a') \right] + \lambda H \left(\pi_i(\cdot \mid s') \right) \right] \\ & \qquad \qquad \text{since } E_{a' \sim \pi_i} \left[Q_{soft}^{\pi_i}(s',a') \right] + \lambda H \left(\pi_i(\cdot \mid s') \right) \\ & \qquad \qquad \leq E_{a' \sim \pi_{i+1}} \left[Q_{soft}^{\pi_i}(s',a') \right] + \lambda H \left(\pi_{i+1}(\cdot \mid s') \right) \\ & \leq R(s,a) + \gamma E_{s'} \left[E_{a' \sim \pi_{i+1}} \left[Q_{soft}^{\pi_i}(s',a') \right] + \lambda H \left(\pi_{i+1}(\cdot \mid s') \right) \right] \\ & \leq \cdots \quad \text{repeatedly apply} \\ & \leq \cdots \quad Q_{soft}^{\pi_i}(s',a') \leq R(s',a') + \gamma E_{s''} \left[E_{a'' \sim \pi_{i+1}} \left[Q_{soft}^{\pi_i}(s'',a'') \right] + \lambda H \left(\pi_{i+1}(\cdot \mid s'') \right) \right] \\ & \leq Q_{soft}^{\pi_{i+1}}(s,a) \end{split}$$

Convergence to Optimal Q_{soft}^* and π_{soft}^*

• Theorem 2: When $\epsilon=0$, soft policy iteration converges to optimal Q_{soft}^* and π_{soft}^* .

Proof:

- We know that $Q^{\pi_{i+1}}(s,a) \ge Q^{\pi_i}(s,a) \ \forall s,a$ according to Theorem 1
- Since the Q-functions are upper bounded by

$$(\max_{s,a} R(s,a) + H(uniform))/(1-\gamma)$$

then soft policy iteration converges

– At convergence, $Q^{\pi_{i-1}}=Q^{\pi_i}$ and therefore the Q-function satisfies Bellman's equation:

$$Q_{soft}^{\pi_{i-1}}(s,a) = Q_{soft}^{\pi_i}(s,a) = R(s,a) + \gamma \sum_{s'} \Pr(s'|s,a) \underbrace{\max_{a'}}_{a'} Q_{soft}^{\pi_{i-1}}(s',a')$$

Soft Actor-Critic

- RL version of soft policy iteration
- Use neural networks to represent policy and value function
- At each policy improvement step, project new policy in the space of parameterized neural nets

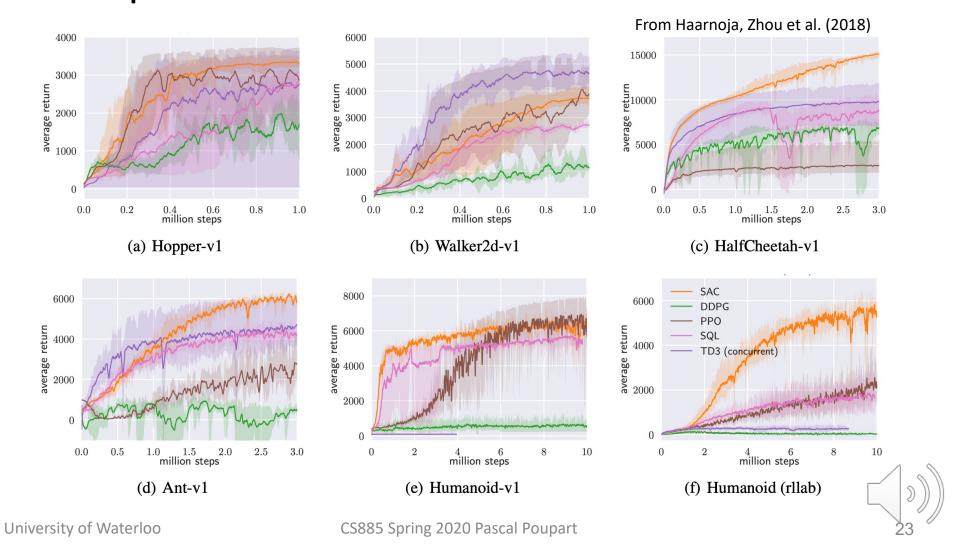

Soft Actor Critic (SAC)

```
Initialize weights w, \overline{w}, \theta at random in [-1,1]
Observe current state s
Loop
           Sample action a \sim \pi_{\theta}(\cdot | s) and execute it
           Receive immediate reward r
           Observe new state s'
           Add (s, a, s', r) to experience buffer
           Sample mini-batch of experiences from buffer
           For each experience (\hat{s}, \hat{a}, \hat{s}', \hat{r}) in mini-batch
                      Sample \hat{a}' \sim \pi_{\theta}(\cdot | \hat{s}')
                     \text{Gradient: } \frac{\partial \textit{Err}}{\partial \textit{w}} = \left[ Q_{\textit{w}}^{\textit{soft}}(\hat{\textit{s}}, \hat{\textit{a}}) - \hat{\textit{r}} - \gamma [Q_{\overline{\textit{w}}}^{\textit{soft}}(\hat{\textit{s}}', \hat{\textit{a}}') + \lambda H(\pi_{\theta}(\cdot \mid \hat{\textit{s}}'))] \right] \frac{\partial Q_{\textit{w}}^{\textit{soft}}(\hat{\textit{s}}, \hat{\textit{a}})}{\partial \textit{w}}
                      Update weights: \mathbf{w} \leftarrow \mathbf{w} - \alpha \frac{\partial Err}{\partial \mathbf{w}}
                     Update policy: \theta \leftarrow \theta - \alpha \frac{\partial \text{KL}(\pi_{\theta} | softmax(Q_{\overline{w}}^{soft}/\lambda))}{2}
           Update state: s \leftarrow s'
           Every c steps, update target: \overline{w} \leftarrow w
```
