

Lecture 8a: Model-Based RL

CS885 Reinforcement Learning

2025-01-30

Complementary readings: [SutBar] Chap. 8

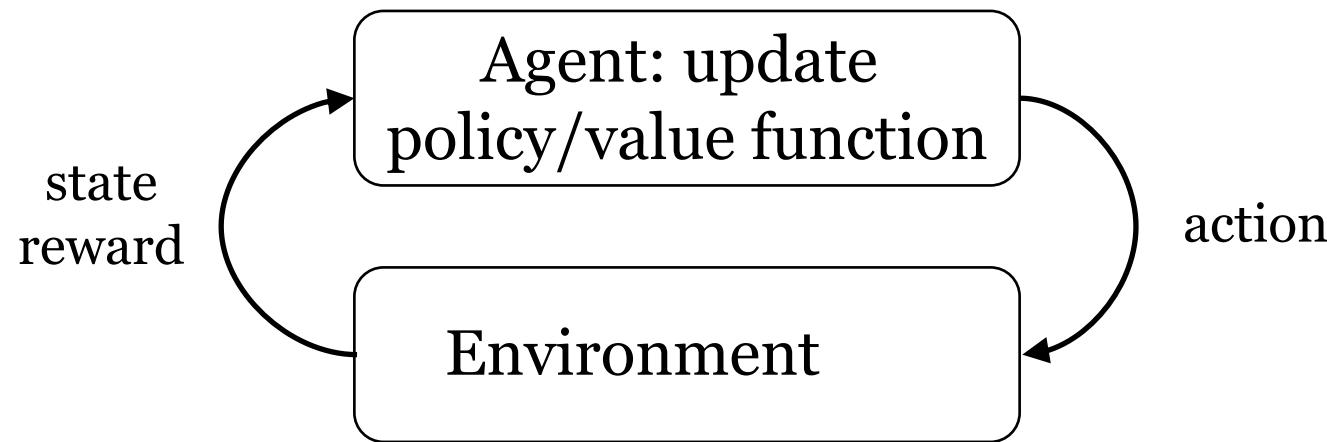

Pascal Poupart
David R. Cheriton School of Computer Science

Outline

- Model-based RL
- Dyna
- Monte-Carlo Tree Search

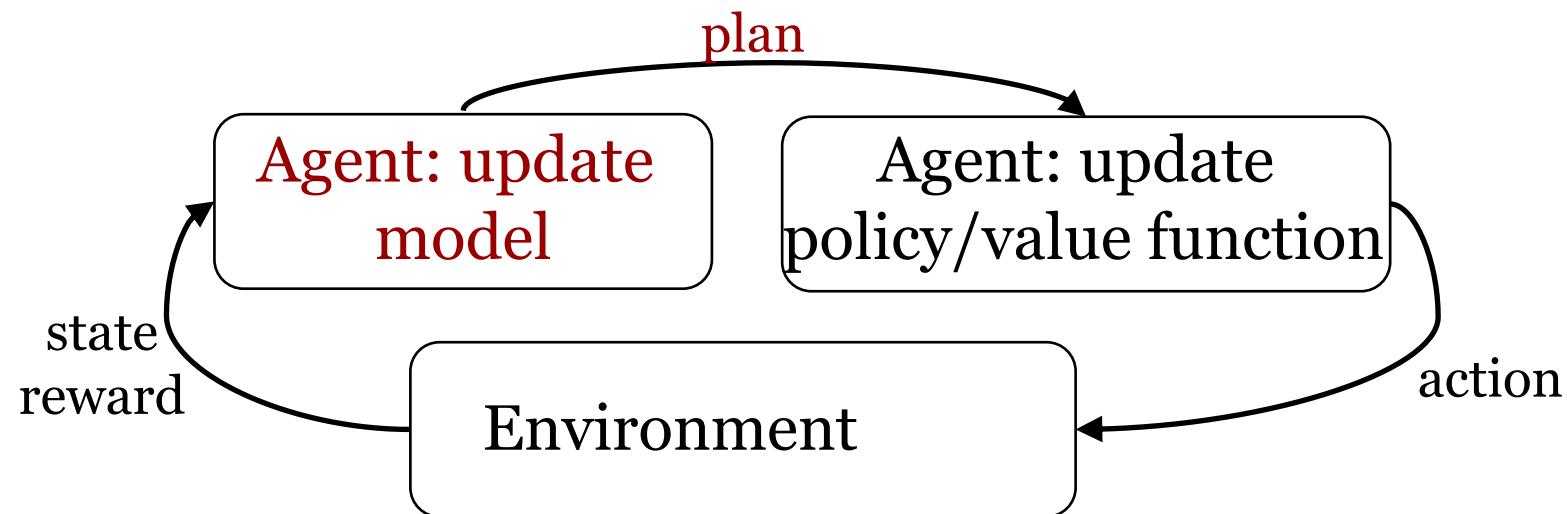

Model-free Online RL

- No explicit transition or reward models
 - Q-learning: **value-based method**
 - Policy gradient: **policy-based method**
 - Actor critic: **policy and value-based method**

Model-based Online RL

- Learn explicit transition and/or reward model
 - Plan based on the model
 - Benefit: Increased sample efficiency
 - Drawback: Increased complexity

Maze Example

r	r	r	+1
u		u	-1
u	l	l	l

1 2 3 4

$$\gamma = 1$$

Reward is -0.04 for non-terminal states

We need to learn all the transition probabilities!

$$(1,1) \rightarrow (1,2) \rightarrow (1,3) \rightarrow (1,2) \rightarrow (1,3) \rightarrow (2,3) \rightarrow (3,3) \rightarrow (4,3)_{+1}$$

$$(1,1) \rightarrow (1,2) \rightarrow (1,3) \rightarrow (2,3) \rightarrow (3,3) \rightarrow (3,2) \rightarrow (3,3) \rightarrow (4,3)_{+1}$$

$$(1,1) \rightarrow (2,1) \rightarrow (3,1) \rightarrow (3,2) \rightarrow (4,2)_{-1}$$

$$\left. \begin{array}{l} P((2,3)|(1,3),r) = 2/3 \\ P((1,2)|(1,3),r) = 1/3 \end{array} \right\} \text{Use this information in}$$

$$V^*(s) = \max_a R(s, a) + \gamma \sum_{s'} \Pr(s'|s, a) V^*(s')$$

Model-based RL

- Idea: at each step
 - Execute action
 - Observe resulting state and reward
 - Update transition and/or reward model
 - Update policy and/or value function

Model-based RL (with Value Iteration)

ModelBasedRL(s)

Repeat

Select and execute a

Observe s' and r

Update counts: $n(s, a) \leftarrow n(s, a) + 1,$

$n(s, a, s') \leftarrow n(s, a, s') + 1$

Update transition: $\Pr(s'|s, a) \leftarrow \frac{n(s, a, s')}{n(s, a)} \quad \forall s'$

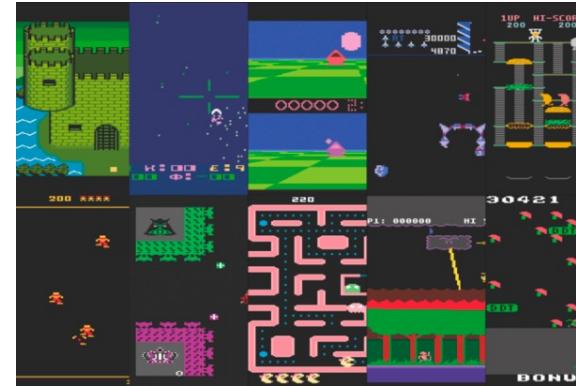

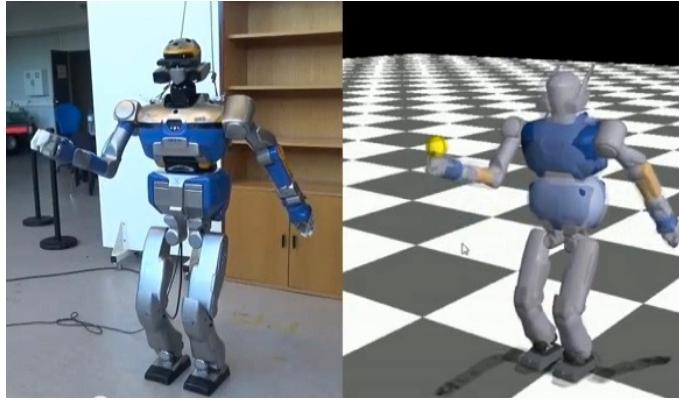

Update reward: $R(s, a) \leftarrow \frac{r + (n(s, a) - 1)R(s, a)}{n(s, a)}$

Solve: $V^*(s) = \max_a R(s, a) + \gamma \sum_{s'} \Pr(s'|s, a) V^*(s') \quad \forall s$
 $s \leftarrow s'$

Until convergence of V^*

Return V^*

Complex Models

- Use function approximation for transition and reward models
 - Linear model: $pdf(s'|s, a) = N(s'|w^T \begin{bmatrix} s \\ a \end{bmatrix}, \sigma^2 I)$
 - Non-linear models:
 - Stochastic (e.g., Gaussian process): $pdf(s'|s, a) = GP(s|w^T \begin{bmatrix} s \\ a \end{bmatrix}, \sigma^2 I)$
 - Deterministic (e.g., neural network): $s' = T(s, a) = NN(s, a)$

Partial Planning

- In complex models, fully optimizing the policy or value function at each time step is intractable
- Consider partial planning
 - A few steps of Q-learning
 - A few steps of policy gradient

Model-based RL (with Q-learning)

ModelBasedRL(s)

Repeat

Select and execute a , observe s' and r

Update transition: $w_T \leftarrow w_T - \alpha_T(T(s, a) - s')\nabla_{w_T} T(s, a)$

Update reward: $w_R \leftarrow w_R - \alpha_R(R(s, a) - r)\nabla_{w_R} R(s, a)$

Repeat a few times:

sample \hat{s}, \hat{a} arbitrarily

$\delta \leftarrow R(\hat{s}, \hat{a}) + \gamma \max_{\hat{a}'} Q(T(\hat{s}, \hat{a}), \hat{a}') - Q(\hat{s}, \hat{a})$

Update Q : $w_Q \leftarrow w_Q - \alpha_Q \delta \nabla_{w_Q} Q(\hat{s}, \hat{a})$

$s \leftarrow s'$

Until convergence of Q

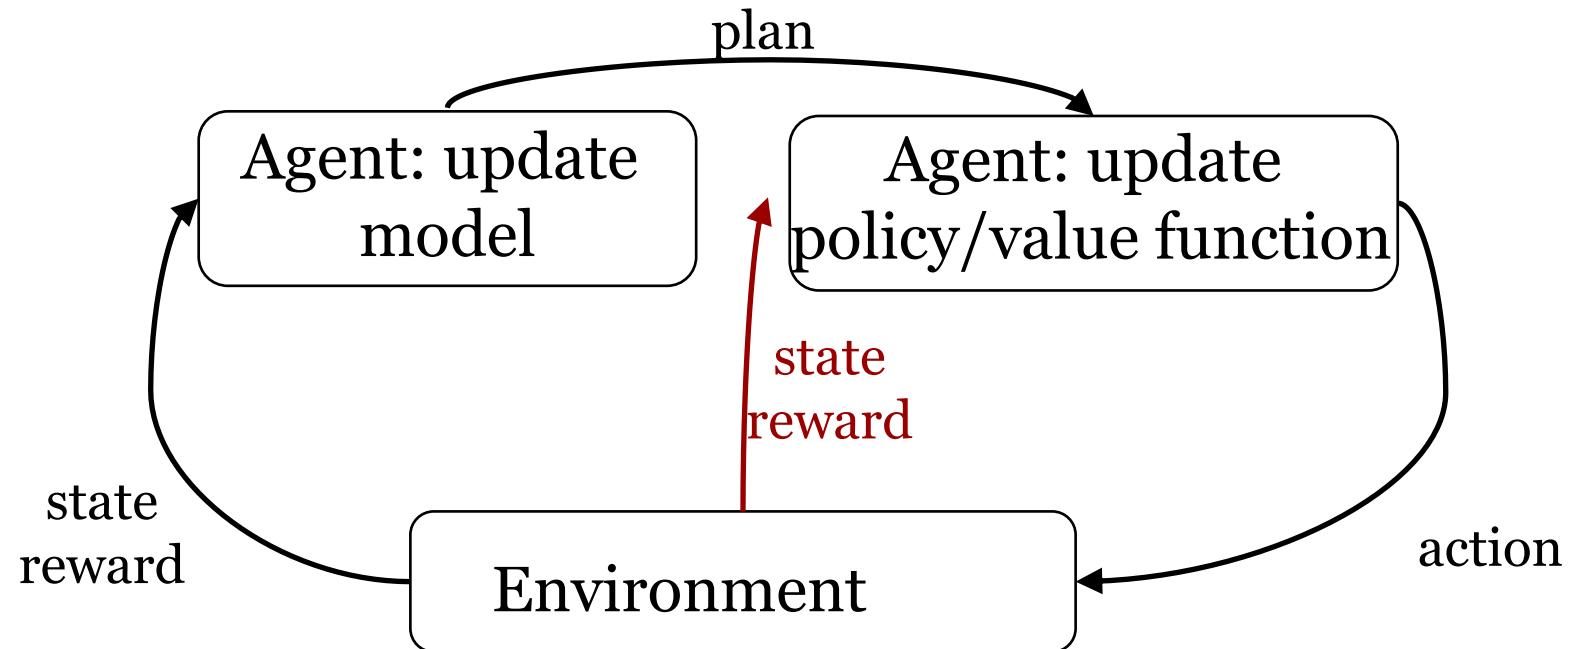

Return Q

Partial Planning vs Replay Buffer

- Previous algorithm is very similar to Model-free Q-learning with a replay buffer
- Instead of updating Q-function based on samples from replay buffer, generate samples from model
- Replay buffer:
 - Simple, real samples, no generalization to other state-action pairs
- Partial planning with a model
 - Complex, simulated samples, generalization to other state-action pairs (can help or hurt)

Dyna

- **Learn explicit transition and/or reward model**
 - Plan based on the model
- **Learn directly from real experience**

Dyna-Q

Dyna-Q(s)

Repeat

Select and execute a , observe s' and r

Update transition: $w_T \leftarrow w_T - \alpha_T(T(s, a) - s')\nabla_{w_T}T(s, a)$

Update reward: $w_R \leftarrow w_R - \alpha_R(R(s, a) - r)\nabla_{w_R}R(s, a)$

$\delta \leftarrow r + \gamma \max_{a'} Q(s', a') - Q(s, a)$

Update Q : $w_Q \leftarrow w_Q - \alpha_Q \delta \nabla_{w_Q} Q(s, a)$

Repeat a few times:

sample \hat{s}, \hat{a} arbitrarily

$\delta \leftarrow R(\hat{s}, \hat{a}) + \gamma \max_{\hat{a}'} Q(T(\hat{s}, \hat{a}), \hat{a}') - Q(\hat{s}, \hat{a})$

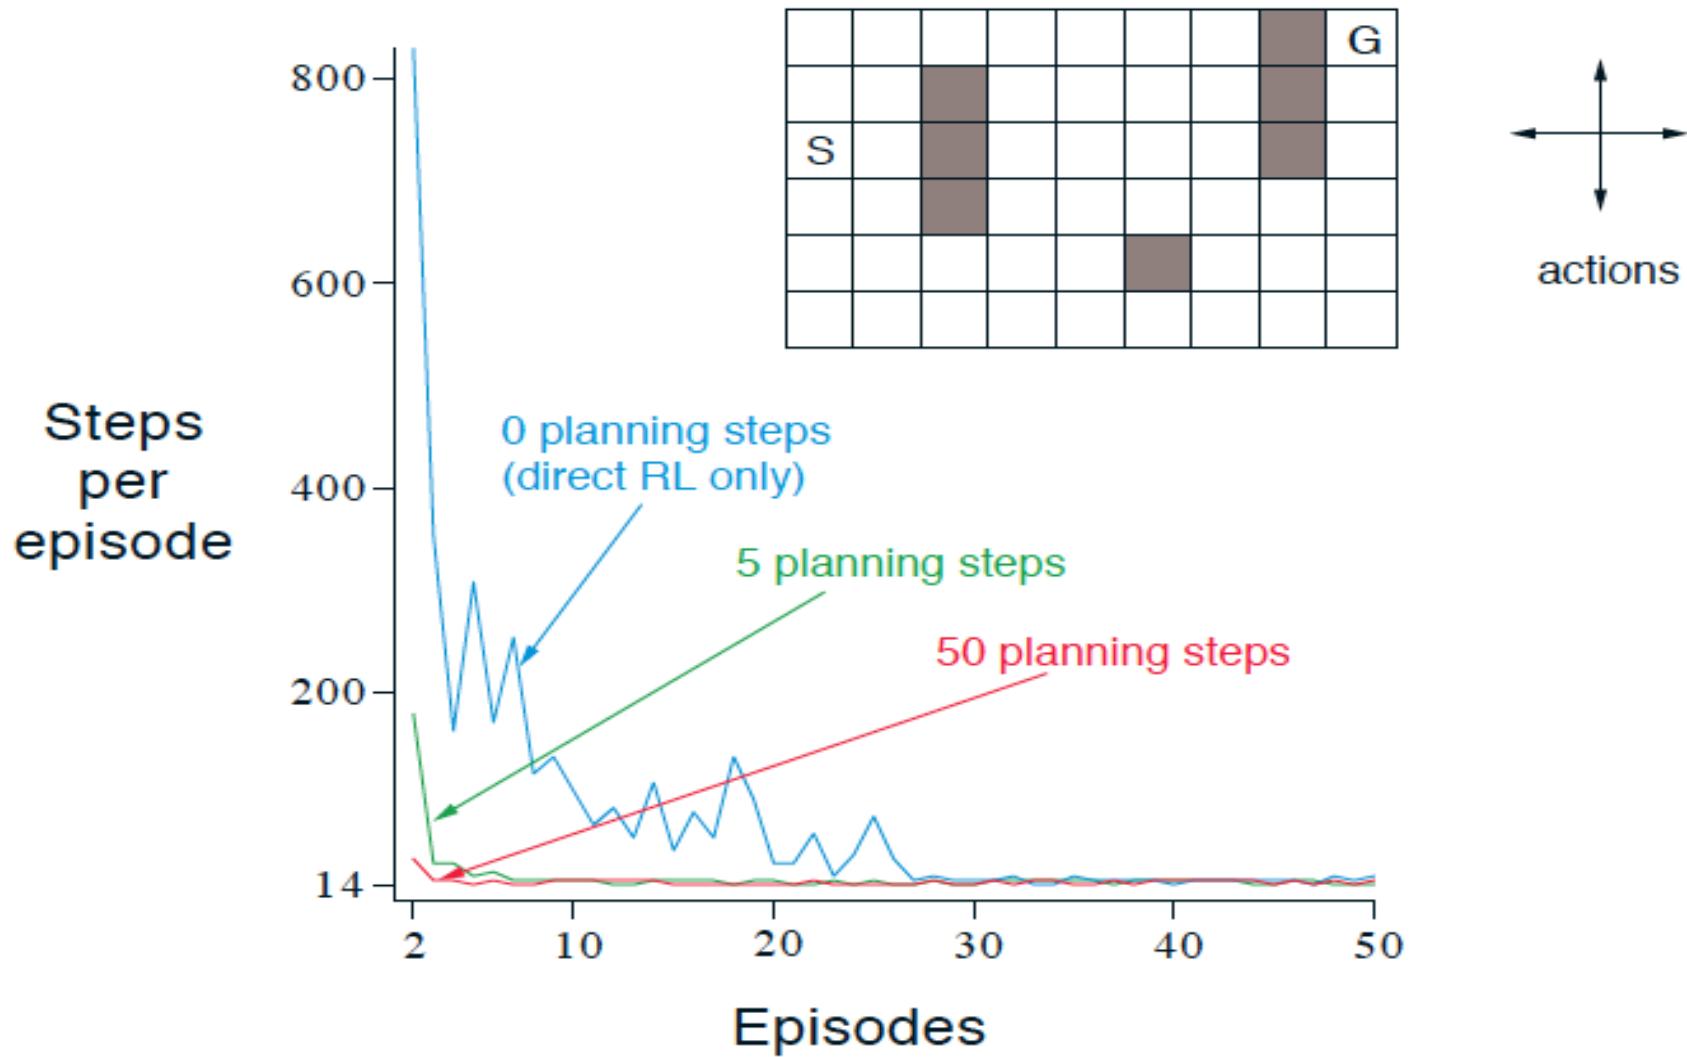

Update Q : $w_Q \leftarrow w_Q - \alpha_Q \delta \nabla_{w_Q} Q(\hat{s}, \hat{a})$

$s \leftarrow s'$

Return Q

Dyna-Q

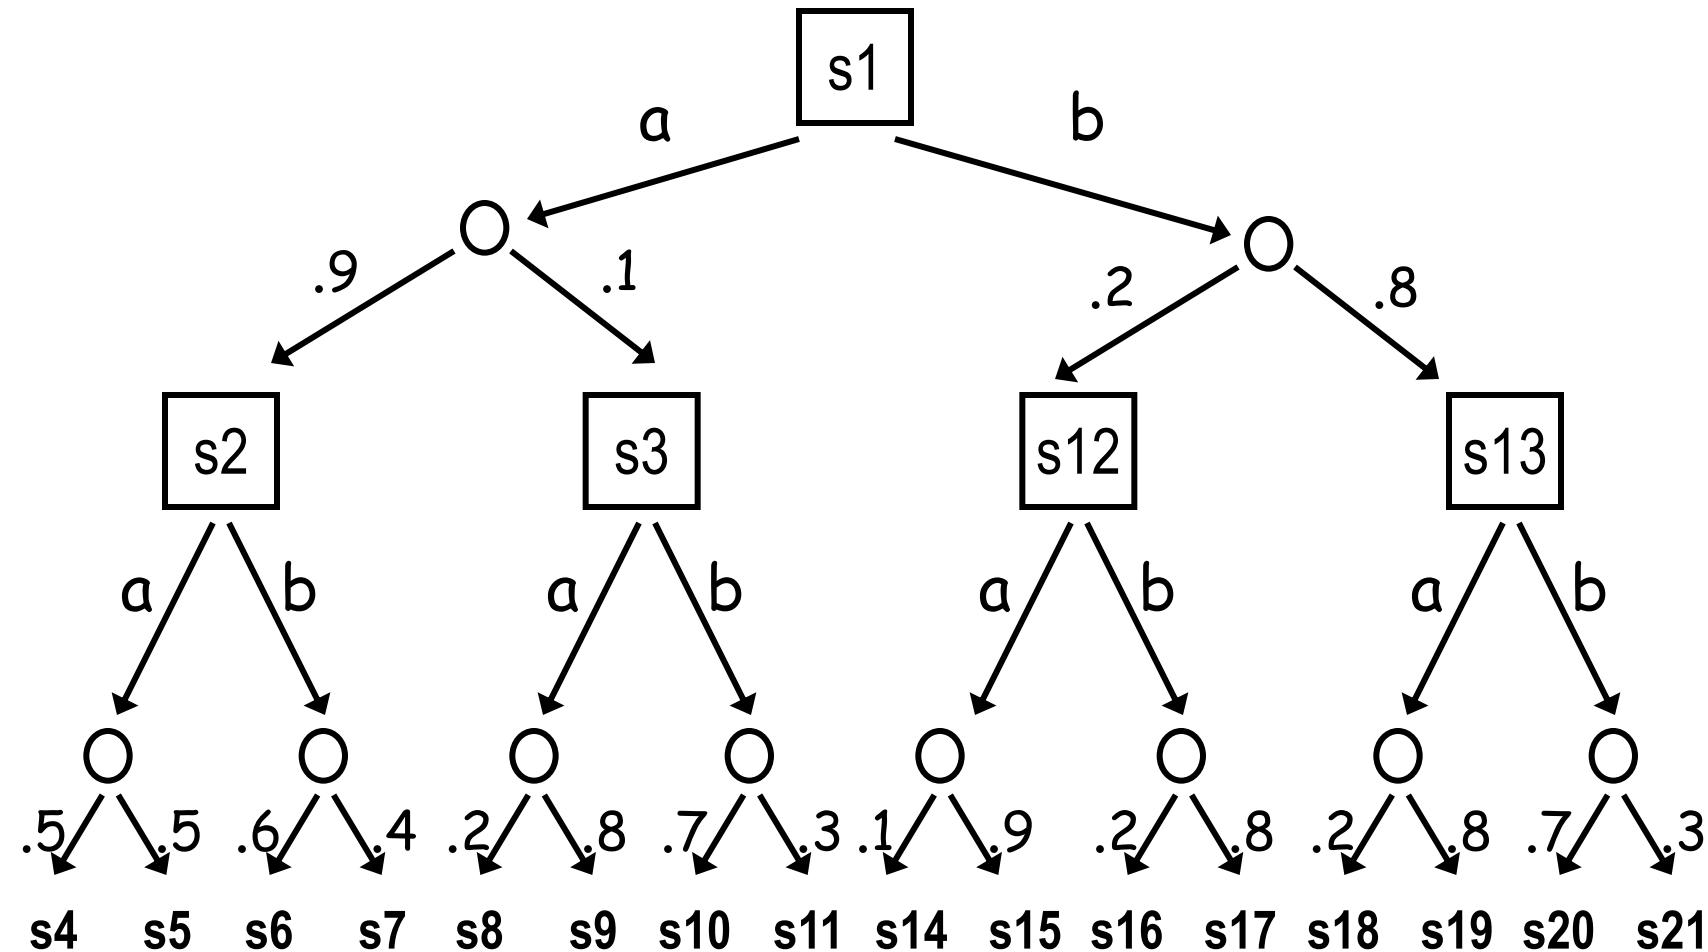

Task:
reach G
from S

Planning from Current State

- Instead of planning at arbitrary states, plan from the current state
 - This helps improve next action
- Monte Carlo Tree Search

Tree Search

Tractable Tree Search

- Combine 3 ideas:

- Leaf nodes: approximate leaf values with value of default policy π

$$Q^*(s, a) \approx Q^\pi(s, a) \approx \frac{1}{n(s,a)} \sum_{k=1}^n G_k$$

- Chance nodes: approximate expectation by sampling from transition model

$$Q^*(s, a) \approx R(s, a) + \gamma \frac{1}{n(s,a)} \sum_{s' \sim \Pr(s'|s,a)} V(s')$$

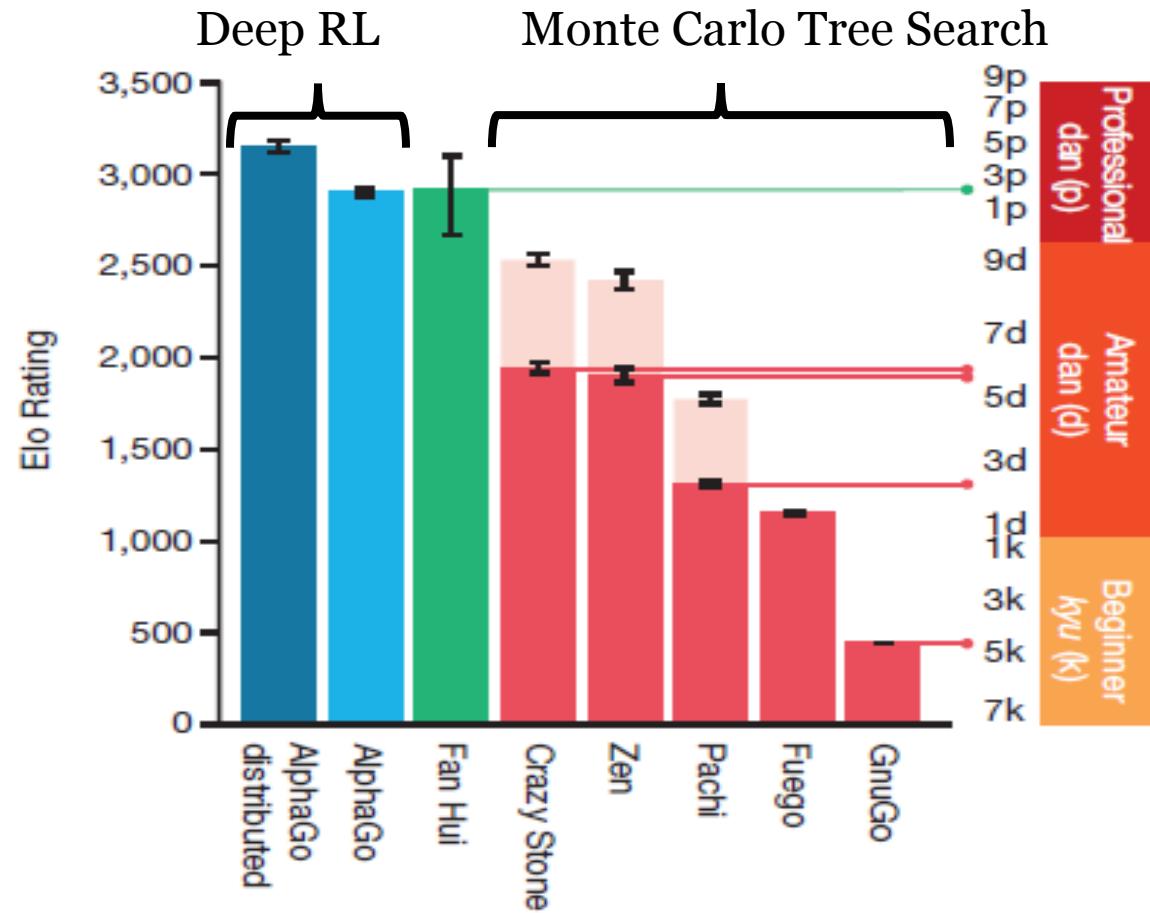

- Decision nodes: expand only most promising actions

$$a^* = \operatorname{argmax}_a Q(s, a) + c \sqrt{\frac{2 \ln n(s)}{n(s,a)}} \quad \text{and} \quad V^*(s) = Q(s, a^*)$$

- Resulting algorithm: Monte Carlo Tree Search

Computer Go

- Oct 2015:

Monte Carlo Tree Search (with upper confidence bound)

UCT(s_0)

```
create root  $node_0$  with state  $state(node_0) \leftarrow s_0$ 
while within computational budget do
     $node_l \leftarrow TreePolicy(node_0)$ 
     $value \leftarrow DefaultPolicy(state(node_l))$ 
     $Backup(node_l, value)$ 
return  $action(BestChild(node_0, 0))$ 
```

TreePolicy($node$)

```
while  $node$  is nonterminal do
    if  $node$  is not fully expanded do
        return  $Expand(node)$ 
    else
         $node \leftarrow BestChild(node, C)$ 
return  $node$ 
```

Monte Carlo Tree Search (continued)

Expand($node$)

choose $a \in$ untried actions of $A(state(node))$
add a new child $node'$ to $node$
with $state(node') \leftarrow T(state(node), a)$
return $node'$

deterministic
transition

BestChild($node, c$)

return $\arg \max_{node' \in children(node)} V(node') + c \sqrt{\frac{(2 \ln n(node))}{n(node')}}$

DefaultPolicy($node$)

while $node$ is not terminal do
sample $a \sim \pi(a|state(node))$
 $s' \leftarrow T(state(node), a)$
return $R(s, a)$

Monte Carlo Tree Search (continued)

Single Player

Backup(*node,value*)

```
while node is not null do
     $V(\textit{node}) \leftarrow \frac{n(\textit{node})V(\textit{node}) + \textit{value}}{n(\textit{node}) + 1}$ 
     $n(\textit{node}) \leftarrow n(\textit{node}) + 1$ 
    node  $\leftarrow \text{parent}(\textit{node})$ 
```

Two Players (adversarial)

BackupMinMax(*node,value*)

```
while node is not null do
     $V(\textit{node}) \leftarrow \frac{n(\textit{node})V(\textit{node}) + \textit{value}}{n(\textit{node}) + 1}$ 
     $n(\textit{node}) \leftarrow n(\textit{node}) + 1$ 
    value  $\leftarrow -\textit{value}$ 
    node  $\leftarrow \text{parent}(\textit{node})$ 
```

AlphaGo

Four steps:

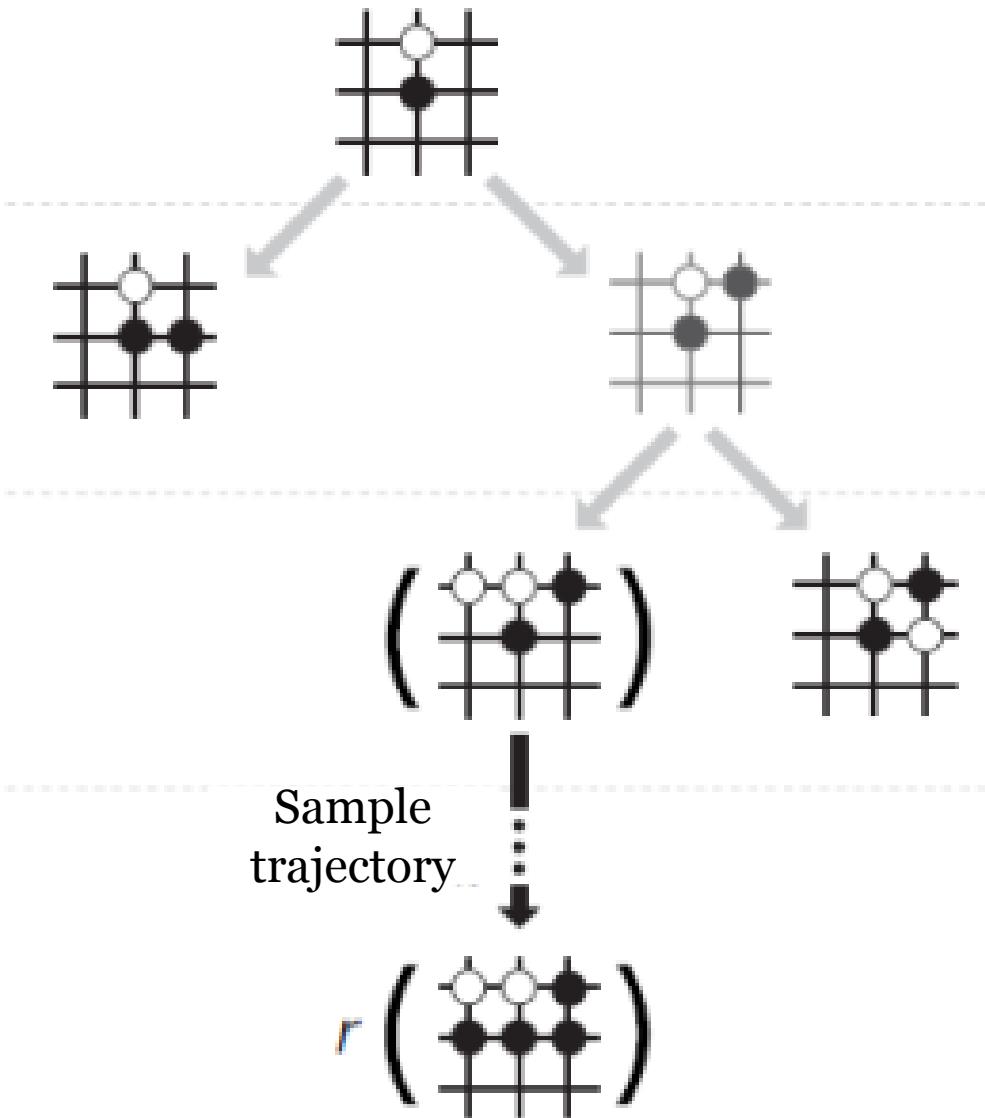

1. Supervised Learning of Policy Networks
2. Policy gradient with Policy Networks
3. Value gradient with Value Networks
4. Searching with Policy and Value Networks
 - Monte Carlo Tree Search variant

Search Tree

- At each edge store

$Q(s, a), \pi(a|s), n(s, a)$

- Where $n(s, a)$ is the visit count of (s, a)

Simulation

- At each node, select edge a^* that maximizes

$$a^* = \operatorname{argmax}_a Q(s, a) + u(s, a)$$

- where $u(s, a) \propto \frac{\pi(a|s)}{1+n(s,a)}$ is an exploration bonus

$$Q(s, a) = \frac{1}{n(s,a)} \sum_i 1_i(s, a) [\lambda V_w(s) + (1 - \lambda) G_i]$$

$$1_i(s, a) = \begin{cases} 1 & \text{if } (s, a) \text{ was visited at iteration } i \\ 0 & \text{otherwise} \end{cases}$$
