

# Dependency Parsing

## Lecture 19: November 13, 2013

CS886-2 Natural Language Understanding  
University of Waterloo

CS886 Lecture Slides (c) 2013 P. Poupart

1

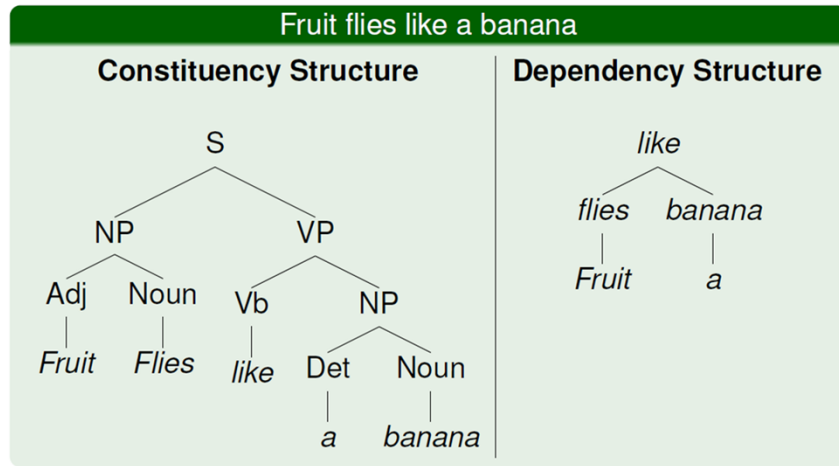

## Parsing

- Constituency Parsing
  - Hierarchical phrase based parsing
- Shallow parsing/syntactic chunking
  - Flat phrase based parsing
- **Dependency Parsing**
  - Identify dependencies/relations between words

CS886 Lecture Slides (c) 2013 P. Poupart

2

## Constituent vs Dependency Tree

CS886 Lecture Slides (c) 2013 P. Poupart

3

## Labelled Dependency Parsing

CS886 Lecture Slides (c) 2013 P. Poupart

4

## Dependency Graph

- **Edge:** head  $\rightarrow$  dependent
  - Head: governing word
  - Dependent: attribute or modifier of the head
- **Labels:**
  - Relation type
  - E.g., ROOT, ATT (attribute), SUBJ (subject), OBJ (object), VC (verb clause), NP (noun phrase), PU (punctuation), TMP (temporal marker), PP (preposition phrase), NMOD (noun modifier)

CS886 Lecture Slides (c) 2013 P. Poupart

5

## Dependency Graph

- Three principles [Robinson, 1970]:
  1. One and only one word is the root
  2. All other words have one and only one parent
  3. If  $w_i$  is the parent of  $w_j$  and  $w_k$  is in between  $w_i$  and  $w_j$  then  $w_k$  must be a descendent of  $w_i$ .
- Notes
  1. and 2. imply that the graph is a **directed tree**
  3. implies that the directed tree is **projective**

CS886 Lecture Slides (c) 2013 P. Poupart

6

## Projective Dependency Graph

- Projective property:
  - Edges do not cross each other
- Most sentences are projective, but not all
  - 10-25% of sentences are non-projective
  - ~1% of arcs do not respect principle 3.
  - Czech, Turkish and German have more freedom in the order of the words, which often leads to non-projective sentences

CS886 Lecture Slides (c) 2013 P. Poupart

7

## Projective vs Non-Projective

Figure 1: A projective dependency graph.

Figure 2: Non-projective dependency graph.

CS886 Lecture Slides (c) 2013 P. Poupart

8

## Algorithms

- Transition-based Parsers
  - Process sentence in a forward fashion
  - Focus on projective sentences (but non-projective extensions possible)
- Graph-based Parsers
  - Process entire sentence at once
  - Focus on non-projective sentences (but projective restrictions possible)

CS886 Lecture Slides (c) 2013 P. Poupart

9

## Graph-based Parsers

- Scoring function
  - Estimate weight for each edge based on labeled data
- Maximum spanning Tree
  - Search for directed spanning tree that maximizes the sum of the weights of the edges
- Label edges
  - Estimate the labels by sequence tagging

CS886 Lecture Slides (c) 2013 P. Poupart

10

## Maximum Spanning Tree

- Suppose we have a weight for each possible edge between any pair of nodes
- Finding the best dependency tree can be cast as a maximum spanning tree problem
  - Non-projective tree:
    - Plain maximum spanning tree (MST)
    - Complexity:  $O(n^2)$
  - Projective tree:
    - Constrained spanning tree
    - Complexity:  $O(n^3)$

CS886 Lecture Slides (c) 2013 P. Poupart

11

## Chu-Liu-Edmonds MST

- Maximum Spanning Tree Algorithm
  - Greedily assign highest scoring incoming edge to each vertex
  - If graph is not a tree (there must be a cycle)
    - Contract each cycle into a single node
    - Recursively call MST on compacted graph
    - Expand back the compacted graph
  - Return graph

CS886 Lecture Slides (c) 2013 P. Poupart

12

## Chu-Liu-Edmonds MST

- Contraction

- Replace each cycle by a new node  $c$

- For each  $y \notin \text{cycle}$ : if  $\exists x \in \text{cycle}$

- Add  $c \rightarrow y$  with weight

$$w(c \rightarrow y) = \max_{x \in \text{cycle}} w(x \rightarrow y)$$

- For each  $x \notin \text{cycle}$ : if  $\exists y \in \text{cycle}$

- Add  $x \rightarrow c$  with weight

$$w(x \rightarrow c) = \max_{y \in \text{cycle}} w(x \rightarrow y) - w(\text{pa}(y) \rightarrow y) + \sum_{y' \in \text{cycle}} w(\text{pa}(y') \rightarrow y')$$

## Example

- John saw Mary
