## Why do we sparsify?

Often times graph algorithms for graphs  $G(V, E)$  have runtimes which depend on  $|E|$ . If the graph is dense, i.e.  $|E| = \omega(n^{1+\gamma})$ , for  $\gamma > 0$ , then this may be *too slow*.

We want graph that has *nearly-linear* number of edges  $O(n \cdot \text{poly log } n)$

- Settle for *approximate answers*

## Why do we sparsify?

Often times graph algorithms for graphs  $G(V, E)$  have runtimes which depend on  $|E|$ . If the graph is dense, i.e.  $|E| = \omega(n^{1+\gamma})$ , for  $\gamma > 0$ , then this may be *too slow*.

We want graph that has *nearly-linear* number of edges  $O(n \cdot \text{poly log } n)$

- Settle for *approximate answers*
- Used as primitives in many other algorithms (for instance, max-flow, sparsest cut, etc.)

## Why do we sparsify?

- Used as primitives in many other algorithms (for instance, max-flow, sparsest cut, etc.)
- Applications in network connectivity

# Graph Cuts

## Definition (Graph Cut)

If  $G(V, E, w)$  is a weighted graph, a *cut* is a partition of the vertices into two non-empty sets  $V = S \sqcup \bar{S}$ . The *value* of a cut is the quantity

$$w(S, \bar{S}) := \sum_{e \in E(S, \bar{S})} w_e.$$

# Contraction of Edges

## Definition (Edge Contraction)

Let  $G(V, E)$  be a graph. If  $e = \{u, v\} \in E$  is an edge of  $G$ , then the *contraction* of  $e$  is a new graph  $H(V \cup \{z\} \setminus \{u, v\}, F)$  where we replace the vertices  $u, v$  by *one* vertex  $z$ , and any edge  $\{u, x\} =: f \in E \setminus \{e\}$  is replaced by  $\{z, x\} \in F$ .

## Randomized Minimum Cut

- **Input:** undirected unweighted graph  $G(V, E)$
- **Output:** minimum cut  $(S, \bar{S})$ , with high probability

## Randomized Minimum Cut

- **Input:** undirected unweighted graph  $G(V, E)$
- **Output:** minimum cut  $(S, \bar{S})$ , with high probability
- While there are more than 2 vertices in the graph:
  - Pick uniformly random edge and contract it

## Randomized Minimum Cut

- **Input:** undirected unweighted graph  $G(V, E)$
- **Output:** minimum cut  $(S, \bar{S})$ , with high probability
- While there are more than 2 vertices in the graph:
  - Pick uniformly random edge and contract it
- Output the two subsets encoded by the two remaining vertices.

# Analysis

Why does this work?

**Intuition:** picking a random edge uniformly at random “favours” *small cuts* (i.e. preserves them) with higher probability.

# Analysis

Why does this work?

**Intuition:** picking a random edge uniformly at random “favours” *small cuts* (i.e. preserves them) with higher probability.

## Remark

The value of the minimum cut does not decrease after contraction.

# Analysis

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

# Analysis

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

- Let  $(S, \bar{S})$  be a minimum cut, and  $c := |E(S, \bar{S})|$ . If we never contract an edge from  $E(S, \bar{S})$ , the algorithm succeeds.

# Analysis

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

- Let  $(S, \bar{S})$  be a minimum cut, and  $c := |E(S, \bar{S})|$ . If we never contract an edge from  $E(S, \bar{S})$ , the algorithm succeeds.
- Probability that an edge from  $E(S, \bar{S})$  is contracted in the  $i^{\text{th}}$  iteration (conditioned on cut still alive)

# Analysis

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

- Let  $(S, \bar{S})$  be a minimum cut, and  $c := |E(S, \bar{S})|$ . If we never contract an edge from  $E(S, \bar{S})$ , the algorithm succeeds.
- Probability that an edge from  $E(S, \bar{S})$  is contracted in the  $i^{\text{th}}$  iteration (conditioned on cut still alive)
  - Each vertex is a cut, so each vertex has degree  $\geq c \Rightarrow$

$$\geq \frac{(n-i+1) \cdot c}{2} \text{ edges remain.}$$

# Analysis

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

- Let  $(S, \bar{S})$  be a minimum cut, and  $c := |E(S, \bar{S})|$ . If we never contract an edge from  $E(S, \bar{S})$ , the algorithm succeeds.
- Probability that an edge from  $E(S, \bar{S})$  is contracted in the  $i^{\text{th}}$  iteration (conditioned on cut still alive)
  - Each vertex is a cut, so each vertex has degree  $\geq c \Rightarrow$

$$\geq \frac{(n-i+1) \cdot c}{2} \text{ edges remain.}$$

- Contracting random edge, probability we kill cut  $(S, \bar{S})$  is

$$= |E(S, \bar{S})| \cdot \frac{1}{(\# \text{ edges})} \leq c \cdot \frac{2}{(n-i+1) \cdot c} = \frac{2}{n-i+1}$$

# Analysis

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is **at least**  $2/n(n-1)$ , where  $n = |V|$ .

- Let  $(S, \bar{S})$  be a minimum cut, and  $c := |E(S, \bar{S})|$ . If we never contract an edge from  $E(S, \bar{S})$ , the algorithm succeeds.
- Probability that an edge from  $E(S, \bar{S})$  is contracted in the  $i^{\text{th}}$  iteration (conditioned on cut still alive)

- Each vertex is a cut, so each vertex has degree  $\geq c \Rightarrow$

$$\geq \frac{(n-i+1) \cdot c}{2} \text{ edges remain.}$$

- Contracting random edge, probability we kill cut  $(S, \bar{S})$  is

$$= |E(S, \bar{S})| \cdot \frac{1}{(\# \text{ edges})} \leq c \cdot \frac{2}{(n-i+1) \cdot c} = \frac{2}{n-i+1}$$

- $\Pr[(S, \bar{S}) \text{ survives}] \geq (1 - 2/n) \cdot (1 - 3/n) \cdots (1 - 2/3) = 2/n(n-1)$

Hmmmmm, this is not with high probability...

- To improve success probability, repeat this randomized procedure  $t$  times (for which  $t$ ?)
- If we repeat for  $t$  times, failure probability is

$$\leq \left(1 - \frac{2}{n(n-1)}\right)^t$$

## Hmmmmm, this is not with high probability...

- To improve success probability, repeat this randomized procedure  $t$  times (for which  $t$ ?)
- If we repeat for  $t$  times, failure probability is

$$\leq \left(1 - \frac{2}{n(n-1)}\right)^t$$

- setting  $t = 2n(n-1)$  then

$$\leq \left(1 - \frac{2}{n(n-1)}\right)^{2n(n-1)} \leq \exp\left(-\frac{2t}{n(n-1)}\right) = e^{-4}$$

## Hmmmmmm, this is not with high probability...

- **Running time:** One execution implemented in  $O(n^2)$ , so  $t$  executions in time  $O(n^2 t) = O(n^4)$ .
- You will work on some running time improvements in your homework!

# Combinatorial Application

## Theorem (Karger)

*The probability that the algorithm outputs a minimum cut is **at least**  $2/n(n-1)$ , where  $n = |V|$ .*

# Combinatorial Application

## Theorem (Karger)

*The probability that the algorithm outputs a minimum cut is **at least**  $2/n(n-1)$ , where  $n = |V|$ .*

## Corollary

*There are at most  $O(n^2)$  minimum cuts in an undirected graph.*

# Combinatorial Application

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

## Corollary

There are at most  $O(n^2)$  minimum cuts in an undirected graph.

- Each minimum cut survives with probability  $\Omega(1/n^2)$
- Events that two different cuts survive are disjoint

# Combinatorial Application

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

## Corollary

There are at most  $O(n^2)$  minimum cuts in an undirected graph.

- Each minimum cut survives with probability  $\Omega(1/n^2)$
- Events that two different cuts survive are disjoint
- Non-trivial statement to prove using other arguments!

# Combinatorial Application

## Theorem (Karger)

The probability that the algorithm outputs a minimum cut is *at least*  $2/n(n-1)$ , where  $n = |V|$ .

## Corollary

There are at most  $O(n^2)$  minimum cuts in an undirected graph.

- Each minimum cut survives with probability  $\Omega(1/n^2)$
- Events that two different cuts survive are disjoint
- Non-trivial statement to prove using other arguments!

This is all good, but we haven't "sparsified" anything so far!

# Graph Sparsification

## Definition (Weight of a cut)

Let  $G(V, E, w)$  be undirected weighted graph. For any cut  $(S, \bar{S})$ , let the weight of  $(S, \bar{S})$  be

$$w(S, \bar{S}) := \sum_{e \in E(S, \bar{S})} w(e).$$

# Graph Sparsification

## Definition (Weight of a cut)

Let  $G(V, E, w)$  be undirected weighted graph. For any cut  $(S, \bar{S})$ , let the weight of  $(S, \bar{S})$  be

$$w(S, \bar{S}) := \sum_{e \in E(S, \bar{S})} w(e).$$

## Definition (Sparse Graph)

We say that a graph  $G(V, E)$  is *sparse* if  $|E| = \tilde{O}(|V|)$ .

# Graph Sparsification

## Definition (Weight of a cut)

Let  $G(V, E, w)$  be undirected weighted graph. For any cut  $(S, \bar{S})$ , let the weight of  $(S, \bar{S})$  be

$$w(S, \bar{S}) := \sum_{e \in E(S, \bar{S})} w(e).$$

## Definition (Sparse Graph)

We say that a graph  $G(V, E)$  is *sparse* if  $|E| = \tilde{O}(|V|)$ .

## Question

How to make a graph sparse (nearly linear # edges) while approximating the *value* of *every cut* of a graph?

# Graph Sparsification

- **Input:** graph  $G(V, E, w_G)$ ,  $\varepsilon > 0$ .

$$n = |V|, \quad m = |E|.$$

- **Output:** graph  $H(V, F, w_H)$  such that *for every cut  $(S, \bar{S})$* , we have

$$(1 - \varepsilon) \cdot w_G(S, \bar{S}) \leq w_H(S, \bar{S}) \leq (1 + \varepsilon) \cdot w_G(S, \bar{S})$$

# Graph Sparsification

- **Input:** graph  $G(V, E, w_G)$ ,  $\varepsilon > 0$ .

$$n = |V|, \quad m = |E|.$$

- **Output:** graph  $H(V, F, w_H)$  such that *for every cut  $(S, \bar{S})$* , we have

$$(1 - \varepsilon) \cdot w_G(S, \bar{S}) \leq w_H(S, \bar{S}) \leq (1 + \varepsilon) \cdot w_G(S, \bar{S})$$

- *Assumption (for this class):* the input graph  $G(V, E)$  is unweighted and has minimum cut value  $\Omega(\log n)$  (i.e., a large-ish cut)

# Graph Sparsification

- **Input:** graph  $G(V, E, w_G)$ ,  $\varepsilon > 0$ .

$$n = |V|, \quad m = |E|.$$

- **Output:** graph  $H(V, F, w_H)$  such that *for every cut  $(S, \bar{S})$* , we have

$$(1 - \varepsilon) \cdot w_G(S, \bar{S}) \leq w_H(S, \bar{S}) \leq (1 + \varepsilon) \cdot w_G(S, \bar{S})$$

- *Assumption (for this class):* the input graph  $G(V, E)$  is unweighted and has minimum cut value  $\Omega(\log n)$  (i.e., a large-ish cut)

## Algorithm:

- Let  $p \in (0, 1)$  be a parameter.
- For each edge  $e \in E(G)$ , with probability  $p$ , make  $e$  an edge of  $H$  with weight  $w_H(e) = 1/p$ .

# Graph Sparsification

## Idea:

- Set  $p$  to get correct expected value for both  $\#$  edges in  $H$  and the value of each cut  $(S, \bar{S})$  in  $H$ .

# Graph Sparsification

## Idea:

- Set  $p$  to get correct expected value for both  $\#$  edges in  $H$  and the value of each cut  $(S, \bar{S})$  in  $H$ .
- After that, need to prove concentration around expected values *for all cuts simultaneously!*

# Graph Sparsification

## Idea:

- Set  $p$  to get correct expected value for both  $\#$  edges in  $H$  and the value of each cut  $(S, \bar{S})$  in  $H$ .
- After that, need to prove concentration around expected values *for all cuts simultaneously!*
- Use Chernoff-Hoeffding and assumption that min-cut value is large.

# Graph Sparsification

## Idea:

- Set  $p$  to get correct expected value for both # edges in  $H$  and the value of each cut  $(S, \bar{S})$  in  $H$ .
- After that, need to prove concentration around expected values *for all cuts simultaneously!*
- Use Chernoff-Hoeffding and assumption that min-cut value is large.

## Theorem ([Karger, 1993])

Let  $c$  be the value of the min-cut of  $G$ . Set

$$p = \frac{15 \ln n}{\varepsilon^2 \cdot c}.$$

Graph  $H$  given by algorithm from previous slide approximates all cuts of  $G$  *and* has  $O(p \cdot |E|)$  edges with probability  $\geq 1 - 4/n$ .

## Graph Sparsification

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$X_e = \begin{cases} 1, & \text{if edge } e \text{ **included in } H \\ 0, & \text{otherwise} \end{cases}**$$

# Graph Sparsification

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$X_e = \begin{cases} 1, & \text{if edge } e \text{ **included in } H \\ 0, & \text{otherwise} \end{cases}**$$

- 

$$\mathbb{E}[|F|] = \sum_{e \in E} \mathbb{E}[X_e] = \sum_{e \in E} (p \cdot 1 + (1 - p) \cdot 0) = p \cdot |E|$$

## Graph Sparsification

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$X_e = \begin{cases} 1, & \text{if edge } e \text{ included in } H \\ 0, & \text{otherwise} \end{cases}$$

$$\mathbb{E}[|F|] = \sum_{e \in E} \mathbb{E}[X_e] = \sum_{e \in E} (p \cdot 1 + (1 - p) \cdot 0) = p \cdot |E|$$

$$\begin{aligned} \mathbb{E}[w_H(S, \bar{S})] &= \sum_{e \in E(S, \bar{S})} \mathbb{E}[w_H(e)] = \sum_{e \in E(S, \bar{S})} \left( p \cdot \frac{1}{p} + (1 - p) \cdot 0 \right) \\ &= |E(S, \bar{S})| = k = w_G(S, \bar{S}) \end{aligned}$$

## Graph Sparsification - Concentration

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$w_e = \begin{cases} 1/p, & \text{if edge } e \text{ **included in } H \\ 0, & \text{otherwise} \end{cases}**$$

## Graph Sparsification - Concentration

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$w_e = \begin{cases} 1/p, & \text{if edge } e \text{ **included in } H \\ 0, & \text{otherwise} \end{cases}**$$

- $w_H(S, \bar{S})$  is a sum of independent random variables  $w_e$

## Graph Sparsification - Concentration

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$w_e = \begin{cases} 1/p, & \text{if edge } e \text{ included in } H \\ 0, & \text{otherwise} \end{cases}$$

- $w_H(S, \bar{S})$  is a sum of independent random variables  $w_e$
- Chernoff Bound:

$$\Pr[|w_H(S, \bar{S}) - k| \geq \varepsilon \cdot k] \leq 2 \exp\left(-\frac{\varepsilon^2 kp}{3}\right) = 2n^{-5k/c}$$

## Graph Sparsification - Concentration

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$w_e = \begin{cases} 1/p, & \text{if edge } e \text{ **included in } H \\ 0, & \text{otherwise} \end{cases}**$$

- $w_H(S, \bar{S})$  is a sum of independent random variables  $w_e$
- Chernoff Bound:

$$\Pr[|w_H(S, \bar{S}) - k| \geq \varepsilon \cdot k] \leq 2 \exp\left(-\frac{\varepsilon^2 kp}{3}\right) = 2n^{-5k/c}$$

- Note that  $k \geq c$ , as  $c$  is the weight of the minimum cut

## Graph Sparsification - Concentration

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$w_e = \begin{cases} 1/p, & \text{if edge } e \text{ **included in } H \\ 0, & \text{otherwise} \end{cases}**$$

- $w_H(S, \bar{S})$  is a sum of independent random variables  $w_e$
- Chernoff Bound:

$$\Pr[|w_H(S, \bar{S}) - k| \geq \varepsilon \cdot k] \leq 2 \exp\left(-\frac{\varepsilon^2 kp}{3}\right) = 2n^{-5k/c}$$

- Note that  $k \geq c$ , as  $c$  is the weight of the minimum cut
- This is probability of *single cut* deviating from its mean... How can we handle the *exponentially many* cuts in the graph?

## Graph Sparsification - Concentration

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$w_e = \begin{cases} 1/p, & \text{if edge } e \text{ included in } H \\ 0, & \text{otherwise} \end{cases}$$

- $w_H(S, \bar{S})$  is a sum of independent random variables  $w_e$
- Chernoff Bound:

$$\Pr[|w_H(S, \bar{S}) - k| \geq \varepsilon \cdot k] \leq 2 \exp\left(-\frac{\varepsilon^2 kp}{3}\right) = 2n^{-5k/c}$$

- Note that  $k \geq c$ , as  $c$  is the weight of the minimum cut
- This is probability of *single cut* deviating from its mean... How can we handle the *exponentially many* cuts in the graph?
- **Observation:** probability that large cut violated is *much smaller*, and there are *not many small cuts*!

## Graph Sparsification - Concentration

- Take a cut  $(S, \bar{S})$ . Suppose  $k := w_G(S, \bar{S})$ . Let

$$w_e = \begin{cases} 1/p, & \text{if edge } e \text{ included in } H \\ 0, & \text{otherwise} \end{cases}$$

- $w_H(S, \bar{S})$  is a sum of independent random variables  $w_e$
- Chernoff Bound:

$$\Pr[|w_H(S, \bar{S}) - k| \geq \varepsilon \cdot k] \leq 2 \exp\left(-\frac{\varepsilon^2 kp}{3}\right) = 2n^{-5k/c}$$

- Note that  $k \geq c$ , as  $c$  is the weight of the minimum cut
- This is probability of *single cut* deviating from its mean... How can we handle the *exponentially many* cuts in the graph?
- **Observation:** probability that large cut violated is *much smaller*, and there are *not many small cuts*!
- So we can do a clever union bound!

# Number of Cuts Lemma

## Lemma (Number of small cuts)

*If  $c$  is the size of the minimum cut in our graph, then the number of cuts with at most  $\alpha \cdot c$  edges for  $\alpha \geq 1$  is at most  $n^{2\alpha}$ .*

# Number of Cuts Lemma

## Lemma (Number of small cuts)

*If  $c$  is the size of the minimum cut in our graph, then the number of cuts with at most  $\alpha \cdot c$  edges for  $\alpha \geq 1$  is at most  $n^{2\alpha}$ .*

**Practice problem:** generalize our earlier proof on the # minimum cuts to this case.

## Union Bound on # Cuts

$$\Pr[\text{some cut is violated}] \leq \sum_{S \subseteq V} \Pr[(S, \bar{S}) \text{ is violated}]$$

## Union Bound on # Cuts

$$\begin{aligned} \Pr[\text{some cut is violated}] &\leq \sum_{S \subseteq V} \Pr[(S, \bar{S}) \text{ is violated}] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} \sum_{\substack{S \subseteq V \\ \alpha c \leq w_G(S, \bar{S}) \leq 2 \cdot \alpha c}} \Pr[(S, \bar{S}) \text{ is violated}] \end{aligned}$$

## Union Bound on # Cuts

$$\begin{aligned} \Pr[\text{some cut is violated}] &\leq \sum_{S \subseteq V} \Pr[(S, \bar{S}) \text{ is violated}] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} \sum_{\substack{S \subseteq V \\ \alpha c \leq |w_G(S, \bar{S})| \leq 2 \cdot \alpha c}} \Pr[(S, \bar{S}) \text{ is violated}] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} n^{4\alpha} \cdot \Pr[(S, \bar{S}) \text{ is violated} \mid \alpha c \leq |w_G(S, \bar{S})| \leq 2 \cdot \alpha c] \end{aligned}$$

## Union Bound on # Cuts

$$\begin{aligned} \Pr[\text{some cut is violated}] &\leq \sum_{S \subseteq V} \Pr[(S, \bar{S}) \text{ is violated}] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} \sum_{\substack{S \subseteq V \\ \alpha c \leq |w_G(S, \bar{S})| \leq 2 \cdot \alpha c}} \Pr[(S, \bar{S}) \text{ is violated}] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} n^{4\alpha} \cdot \Pr[(S, \bar{S}) \text{ is violated} \mid \alpha c \leq |w_G(S, \bar{S})| \leq 2 \cdot \alpha c] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} n^{4\alpha} \cdot 2n^{-5\alpha c/c} \\ &= \sum_{\alpha=1,2,4,8,\dots} n^{-\alpha} \leq 4/n \end{aligned}$$

## Union Bound on # Cuts

$$\begin{aligned} \Pr[\text{some cut is violated}] &\leq \sum_{S \subseteq V} \Pr[(S, \bar{S}) \text{ is violated}] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} \sum_{\substack{S \subseteq V \\ \alpha c \leq |w_G(S, \bar{S})| \leq 2 \cdot \alpha c}} \Pr[(S, \bar{S}) \text{ is violated}] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} n^{4\alpha} \cdot \Pr[(S, \bar{S}) \text{ is violated} \mid \alpha c \leq |w_G(S, \bar{S})| \leq 2 \cdot \alpha c] \\ &\leq \sum_{\alpha=1,2,4,8,\dots} n^{4\alpha} \cdot 2n^{-5\alpha c/c} \\ &= \sum_{\alpha=1,2,4,8,\dots} n^{-\alpha} \leq 4/n \end{aligned}$$

Another application of Chernoff gives us that  $H$  has the right number of edges  $|F| \approx p \cdot |E|$  (i.e., sparse)

## How to remove the assumption?

- Assumed that the graph has large min-cut value ( $c = \Omega(\log n)$ ).

## How to remove the assumption?

- Assumed that the graph has large min-cut value ( $c = \Omega(\log n)$ ).
- Without min-cut assumption, uniform sampling won't work

## How to remove the assumption?

- Assumed that the graph has large min-cut value ( $c = \Omega(\log n)$ ).
- Without min-cut assumption, uniform sampling won't work
- **[Benczur, Karger 1996]**: without minimum cut assumption, just sample non-uniformly in clever way!

## How to remove the assumption?

- Assumed that the graph has large min-cut value ( $c = \Omega(\log n)$ ).
- Without min-cut assumption, uniform sampling won't work
- **[Benczur, Karger 1996]**: without minimum cut assumption, just sample non-uniformly in clever way!
- Sample edge with probability proportional to “connectivity” of two endpoints (i.e., how relevant is the edge between them?)

## How to remove the assumption?

- Assumed that the graph has large min-cut value ( $c = \Omega(\log n)$ ).
- Without min-cut assumption, uniform sampling won't work
- **[Benczur, Karger 1996]:** without minimum cut assumption, just sample non-uniformly in clever way!
- Sample edge with probability proportional to “connectivity” of two endpoints (i.e., how relevant is the edge between them?)
- **Strong Connectivity:** a  $k$ -strong component is a maximal induced subgraph that is  $k$ -edge-connected. For each edge  $e$ , let  $s_e$  be the maximum value  $k$  such that there exists a  $k$ -strong component containing  $e$ .
