- GoF Design Patterns Book

# Design Patterns #2

**Reid Holmes**

# GoF design patterns

# Composite

- ▶ Intent: “Compose objects into whole-part hierarchies, allowing ?
- ▶ Motivation: For situations where complex artifacts can be composed from multiple elements.
- ▶ Applicability:
  - ▶ For representing whole-part relationships.
  - ▶ For situations when you want your clients to ?

# Composite

- ▶ Structure:
- ▶ Participants:
  - ▶ Component (lowest common denominator)
  - ▶ Leaf
  - ▶ Composite
  - ▶ Client

# Composite

- ▶ Collaborations
  - ▶ Clients interact with component interface; composite objects forward requests to leaves.
- ▶ Consequences:
  - ▶ Allows applications to ?
  - ▶ Easy to add new components.
  - ▶ Negative: can make your app overly general. Hard to restrict how leaves can be composed.

# Composite

- ▶ Implementation:
  1. Explicit parent references can be helpful
  2. Maximize the component interface
  3. Child ordering may matter
  4. Caching for performance
- ▶ Related to:
  - ▶ Often used with **Decorator** and **Visitor** patterns.

# Decorator

- ▶ Intent: “Dynamically add additional responsibilities to structures.”
- ▶ Motivation: Sometimes we want to add new responsibilities to individual objects, not the whole class. Can enclose existing objects with another object.
- ▶ Applicability:
  - ▶ Add responsibilities dynamically and transparently.
  - ▶ Remove responsibilities dynamically.
  - ▶ ?

# Decorator

- ▶ Structure
- ▶ Participants:
  - ▶ Component / concrete component
  - ▶ Decorator / concrete decorator

# Decorator (code ex)

# Decorator

- ▶ Collaborations
  - ▶ Decorators forward requests to component object.
- ▶ Consequences:
  - ▶ More flexible.
  - ▶ Avoids ?
  - ▶ Warn: Decorator & component are not identical.
    - ▶ ?
  - ▶ Negative: Many of little objects.

# Decorator

- ▶ Implementation:
  - ▶ 1) Interface conformance.
  - ▶ 2) Abstract decorator not needed if only one decoration is required.
  - ▶ 2) Keep component classes lightweight.
  - ▶ 3) Changing a skin instead of changing the guts.
- ▶ Related to: Decorators are a kind of single-node **Composite**. Decorators can change the skin, **Strategy** pattern can change the guts.

# Visitor

- ▶ Intent: “Represent operations to be performed on classes of elements.”
- ▶ Motivation: ?
- ▶ Applicability:
  - ▶ When you have a large object structure you want to traverse.
  - ▶ ?
  - ▶ The objects rarely change but the operations may.

# Visitor

- ▶ Structure
- ▶ Participants:
  - ▶ Visitor / ConcreteVisitor
  - ▶ Element / ConcreteElement
  - ▶ ObjectStructure

# Visitor

- ▶ Collaborations:
  - ▶ Client creates the ConcreteVisitor that traverses the object structure.
  - ▶ The visited object calls its corresponding visitor method on the ConcreteVisitor.
- ▶ Consequences:
  - ▶ Adding new operations is easy.
  - ▶ Visitor gathers related operations
  - ▶ Adding ConcreteElement classes is hard.
  - ▶ Accumulating state.
  - ▶ Negative: ?

# Visitor

- ▶ Implementation:
  - ▶ 1) Double dispatch.
  - ▶ 2) Who traverses structure?
- ▶ Related to: Good ad visiting **Composite** structures.

# Command

- ▶ Intent: “Encapsulate requests enabling clients to log / undo them as required.”
- ▶ Motivation: In situations where you need to be able to make requests to objects without knowing anything about the request itself or the receiver of the request, the command pattern enables you to pass requests as objects.
- ▶ Applicability:
  - ▶ ?
  - ▶ ?
  - ▶ Support undo.
  - ▶ Model high-level operations on primitive operations.

# Command

- ▶ Structure
- ▶ Participants:
  - ▶ Command / ConcreteCommand
  - ▶ Client
  - ▶ Invoker
  - ▶ Receiver

# Command

- ▶ Collaborations:
  - ▶ Client creates ConcreteCommand and specifies receiver.
  - ▶ Invoker stores ConcreteCommand object.
  - ▶ Invoker requests execute on Command; stores state for undoing prior to execute (if undoable).
  - ▶ Concrete invokes operations on its receiver to perform request.
- ▶ Consequences:
  - ▶ ?
  - ▶ Commands are first-class objects.
  - ▶ Commands can be assembled into composite.
  - ▶ ?

# Command

- ▶ Implementation:
  - ▶ 1) How smart should a command be?
  - ▶ 2) Support undo/redo.
  - ▶ 3) Avoiding error accumulation in the undo process.
- ▶ Related to: **Composite** commands can be created; the **Memento** pattern can store undo state. Commands often use **Prototype** when they need to be stored for undo/redo.

# iRoadTrip demo

- ▶ Functionality being demonstrated:
  - ▶ Creating a trip.
  - ▶ Joining a trip.
  - ▶ Adding new users to a trip dynamically.
  - ▶ Updating positions dynamically.
- ▶ Not implemented:
  - ▶ Statistics / querying.
  - ▶ Interaction.
  - ▶ Leaving a trip / managing trips.
