# Relational Database Design using E/R

**CS348** 

Instructor: Sujaya Maiyya

# Motivating Example

I want to have a registrar's database. Can you help?

#### It has these requirements ...

Zero or more sections of a course are offered each term. Courses have names and numbers. In each term, the sections of each course are numbered starting with 1.

Most course sections are taught on-site, but a few are taught at off-site locations.

Students have student numbers and names. Each course section is taught by a professor. A professor may teach more than one section in a term, but if a professor teaches more than one section in a term, they are always sections of the same course. Some professors do not teach every term.

Up to 50 students may be registered for a course section. Sections with 5 or fewer students are cancelled.

A student receives a mark for each course in which they are enrolled. Each student has a cumulative grade point average (GPA) which is calculated from all course marks the student has received. I know how to use SQL now!

What tables do you want me to create? What are the primary keys, constraints, queries, ....?

We still need to learn about database design ☺

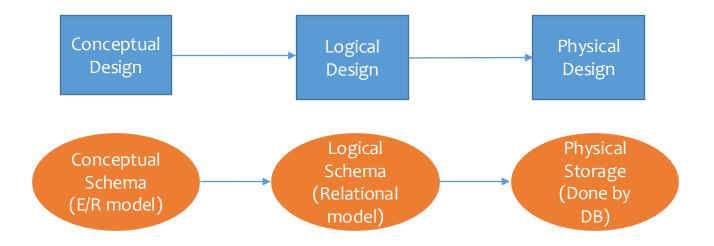

### Database Design

Step 1: Understand the real-world domain being modeled

- → Specify it using a database design model
  - Entity/Relationship (E/R) model

Step 2: Translate specification to the data model of DBMS

- Relational
- → Create DBMS schema

# Database Design

Entity-Relationship (E/R) model

Translating E/R to relational schema

Relational design principles

# Entity-relationship (E/R) model

Historically and still very popular

- Primarily a design model—not directly implemented by DBMS
- Designs represented by E/R diagrams
  - We use E/R diagram styles slightly different from the one covered by the textbook book
  - There are other styles/extensions

#### E/R basics

- Entity: a "thing," like an object
- Entity set: a collection of things of the same type, like a relation of tuples or a class of objects
  - Represented as a rectangle
- Relationship: an association among entities
- Relationship set: a set of relationships of the same type (among same entity sets)
  - Represented as a diamond
- Attributes: properties of entities or relationships, like attributes of tuples or objects
  - Represented as ovals

# An example E/R diagram

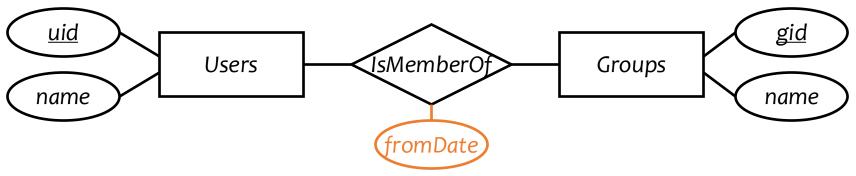

Users are members of groups

- A key of an entity set is represented by <u>underlining</u> all attributes in the key
  - A key is a set of attributes whose values can belong to at most one entity in an entity set—like a key of a relation

### Attributes of relationships

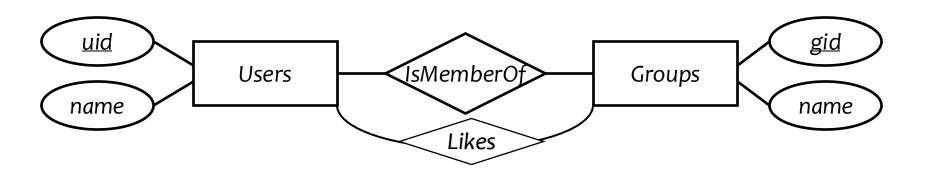

Example: a user belongs to a group since a particular date

- Where do the dates go?
  - With Users?
    - But a user can join multiple groups on different dates
  - With Groups?
    - But different users can join the same group on different dates
  - With IsMemberOf!

#### More on relationships

- There could be multiple relationship sets between the same entity sets
  - Example: Users IsMemberOf Groups; Users Likes Groups
- In a relationship set, each relationship is uniquely identified by the entities it connects
  - Example: Between Bart and "Dead Putting Society", there can be at most one IsMemberOf relationship and at most one Likes relationship

#### More on relationships

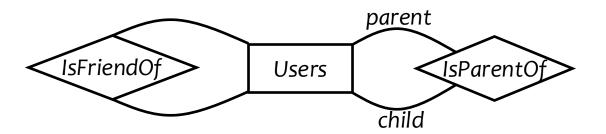

- There could be multiple relationship sets between the same entity sets
  - Example: Users IsMemberOf Groups; Users Likes Groups
- In a relationship set, each relationship is uniquely identified by the entities it connects
  - Example: Between Bart and "Dead Putting Society", there can be at most one *IsMemberOf* relationship and at most one *Likes* relationship
  - What if Bart joins DPS, leaves, and rejoins? How can we modify the design to capture historical membership information?
    - Make an entity set of MembershipRecords

### Roles in relationships

 An entity set may participate more than once in a relationship set

May need to label edges to distinguish roles

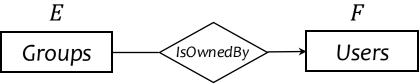

- Examples
  - Users may be parents of others; label needed
  - Users may be friends of each other; label not needed

#### Multiplicity of relationships

- *E* and *F*: entity sets
- Many-many: Each entity in E is related to 0 or more entities in F and vice versa
  - Example: EEach group has many users; Each user belongs to many groups.
- Many-one: Each entity in E is related to 0 or 1 entity in F, but each entity in F is related to 0 or more in E
  - Example: Each group is owned by at most 1 user; Each user can own many groups

Users

<u> ÍsMemberOf</u>

Groups

F

# Multiplicity of relationships

- *E* and *F*: entity sets
- One-many: Each entity in E is related to 0 or more entities in F, but each entity in F is related to 0 or 1 in E
  - Example: Each group has many users; Each user belongs to at most 1 group  $\underline{F}$

Groups

Users

(IsMemberBy

isMember0f

Users

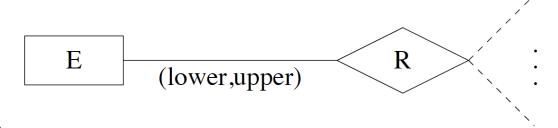

F

Groups

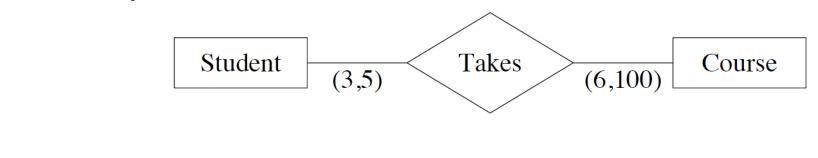

- One-one: Each entity in *E* is related to 0 or 1 entity in *F* and vice versa
  - Example: Each group has at most 1 user; Each user belongs to at most 1 group \_\_\_\_\_\_
- "One" (o or 1) is represented by an arrow

### General cardinality constraints

 General cardinality constraints determine lower and upper bounds on the number of relationships of a given relationship set in which a component entity may participate

Example:

### Total vs. partial participation

- Total participation (indicated by double line): every entity in the entity set participates in at least one relationship in the relationship set
- Partial participation: some entities may not participate in any relationship in the relationship set

Every Student must participate in Advice (i.e., is advised by a faulty) Some faculty may not advice any students

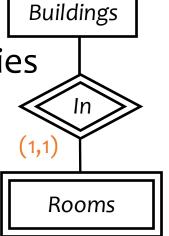

#### Weak entity sets

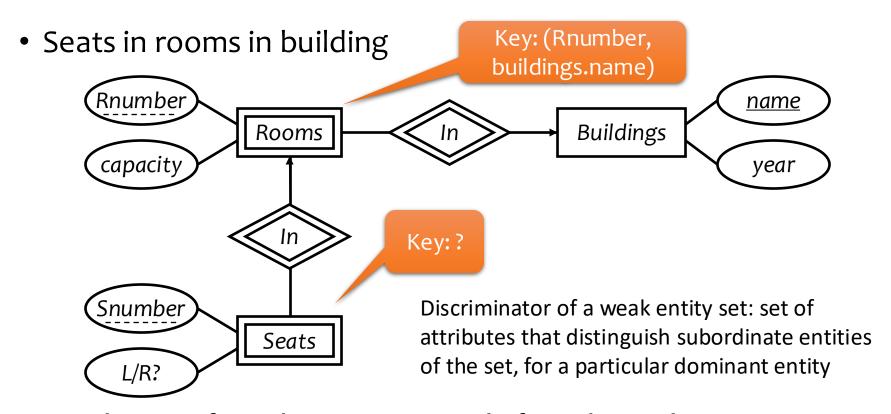

- If entity E's existence depends on entity F, then
  - F is a dominant entity
  - E is a subordinate entity
  - Example: Rooms inside Buildings are partly identified by Buildings' name

Weak entity set: containing subordinate entities

- Drawn as a double rectangle
- The relationship sets are called supporting relationship sets, drawn as double diamonds
- A weak entity set must have a many-to-one or one-to-one + total participation relationship to a distinct entity set

### Weak entity set examples

- Attributes of weak entity sets only form key relative to a given dominant entity 

  discriminator (dotted underline)
- Primary key of a weak entity set: discriminator + primary key of entity set for dominant entities

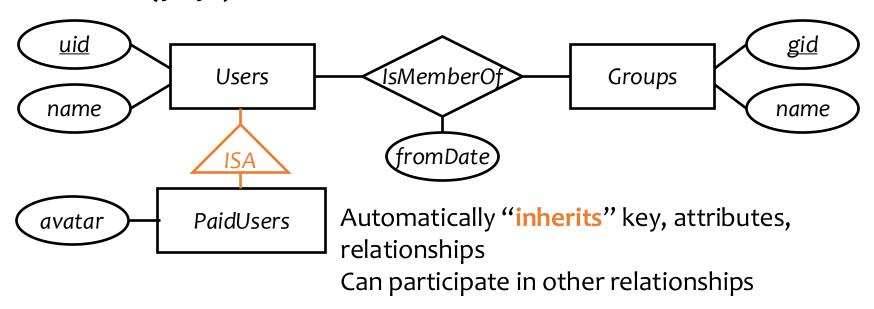

#### Extended E-R features

Specialization

Aggregation (different from SQL aggregation!)

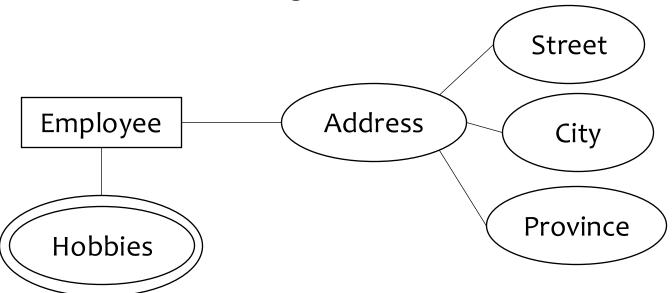

# Specialization or ISA relationships

- Similar to the idea of subclasses in object-oriented programming: subclass = special case, fewer entities, and possibly more properties
  - Represented as a triangle (direction is important)
- Example: paid users are users, but they also get avatars (yay!)

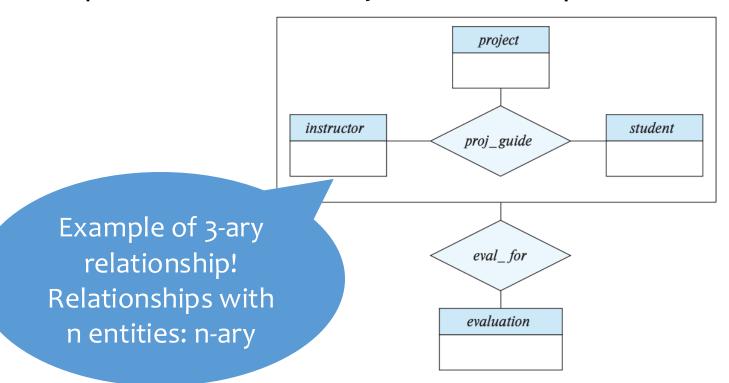

#### Composite and multi-valued attributes

- Composite attributes: composed of fixed number of other attributes
  - E.g. Address
- Multi-valued attributes: attributes that are setvalued
  - e.g. Hobbies (double edges)

# Aggregation

- Aggregation: relationships can be viewed as highlevel entities
- Example: "each instructor guiding a student on a project is required to fill a monthly evaluation report"

### Summary of E/R concepts

- Entity sets
  - Keys
  - Weak entity sets
- Relationship sets
  - Attributes of relationships
  - Multiplicity
  - Roles
  - Supporting relationships (related to weak entity)
  - ISA relationships
- Other extensions:
  - Specialization
  - Aggregation

# Designing an E/R schema

Usually many ways to design an E-R schema

- Points to consider
  - use attribute or entity set?
  - use entity set or relationship set?
  - degrees of relationships?
  - extended features?

### Attributes or Entity Sets?

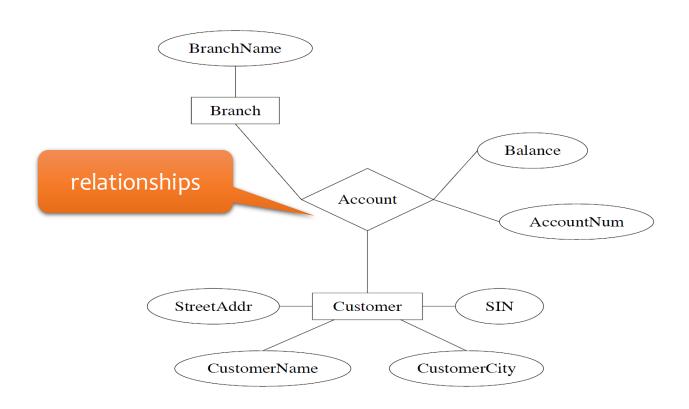

Example: How to model employees' phones?

- Rules of thumb:
  - Do we maintain information about it? E.g., model, make
  - Can several of its kind belong to a single entity? E.g., home, office
  - Can it be missing from some of the entity set's entities?
  - Can it be shared by different entities? E.g., 2 employees share office phone
- → An affirmative answer to any of the above suggests a new entity set.

# Entity Sets or Relationships?

- Example: Customers have a bank account in a bank branch
- Instead of representing accounts as entities, we could represent them as relationships

# A simple methodology

- 1. Recognize entity sets
- 2. Recognize relationship sets and participating entity sets
- 3. Recognize attributes of entity and relationship sets
- 4. Define relationship types and existence dependencies
- Define general cardinality constraints, keys and discriminators
- 6. Draw diagram
- For each step, maintain a log of assumptions motivating the choices, and of restrictions imposed by the choices

#### Design a database representing cities, counties, and states

- For states, record name and capital (city)
- For counties, record name, area, and location (state)
- For cities, record name, population, and location (county and state)

#### Assume the following:

- Names of states are unique
- Names of counties are only unique within a state
- Names of cities are only unique within a county
- A city is always located in a single county
- A county is always located in a single state

What are the entity sets, relationship sets, and their attributes? What are the types of relationships and cardinality constraints, keys, discriminators?

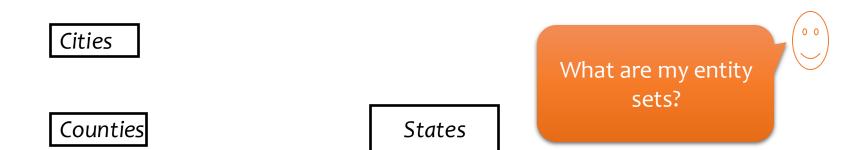

#### Design a database representing cities, counties, and states

- For states, record name and capital (city)
- For counties, record name, area, and location (state)
- For cities, record name, population, and location (county and state)

#### Assume the following:

- Names of states are unique
- Names of counties are only unique within a state
- Names of cities are only unique within a county
- A city is always located in a single county
- A county is always located in a single state

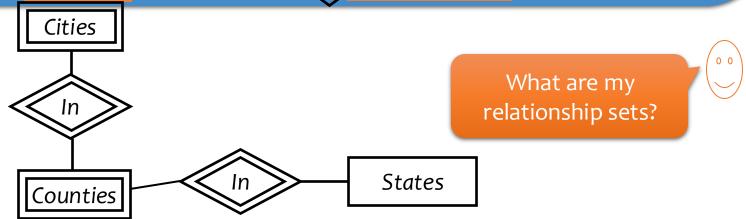

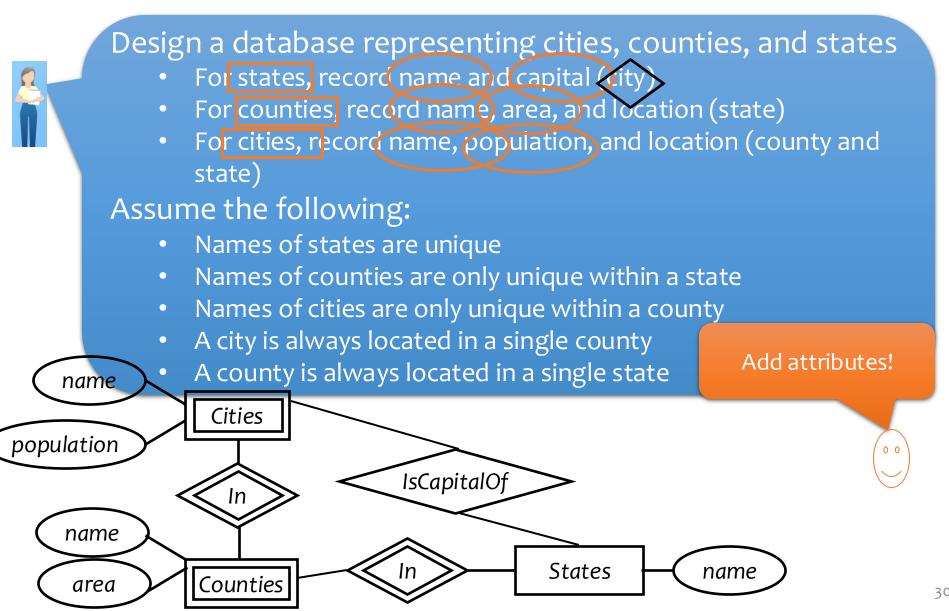

#### Design a database representing cities, counties, and states

- For states, record name and capital (city)
- For counties, record name, area, and location (state)
- For cities, record name, population, and location (county and state)

#### Assume the following:

- Names of states are unique
- Names of counties are only unique within a state
- Names of cities are only unique within a county
- A city is always located in a single county
- A county is always located in a single state

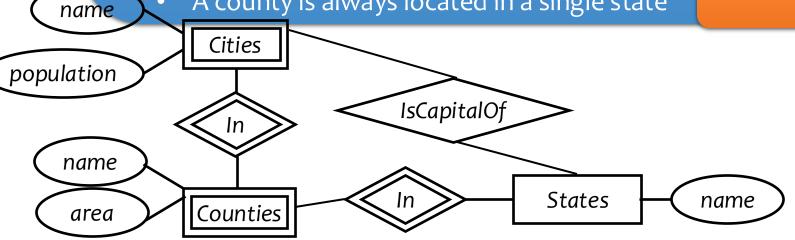

#### Design a database representing cities, counties, and states

- For states, record name and capital (city)
- For counties, record name, area, and location (state)
- For cities, record name, population, and location (county and state)

#### Assume the following:

- Names of states are unique
- Names of counties are only unique within a state
- Names of cities are only unique within a county
- A city is always located in a single county
- A county is always located in a single state

Relationship types?

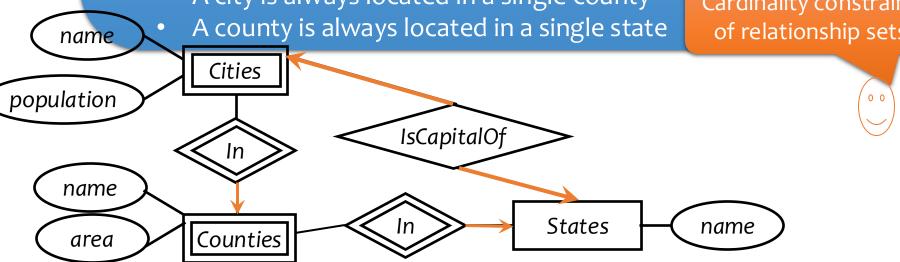

#### Design a database representing cities, counties, and states

- For states, record name and capital (city)
- For counties, record name, area, and location (state)
- For cities, record name, population, and location (county and state)

#### Assume the following:

- Names of states are unique
- Names of counties are only unique within a state
- Names of cities are only unique within a county
- A city is always located in a single county

Cardinality constraints of relationship sets?

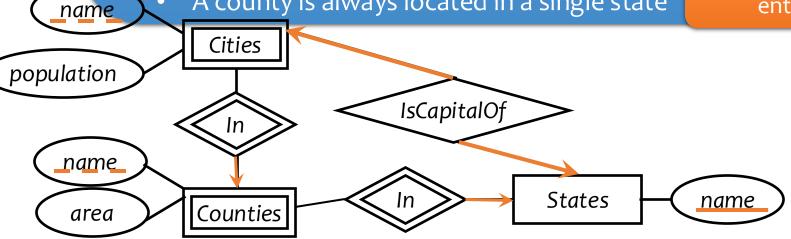

Design a database representing cities, counties, and states

- For states, record name and capital (city)
- For counties, record name, area, and location (state)
- For cities, record name, population, and location (county and state)

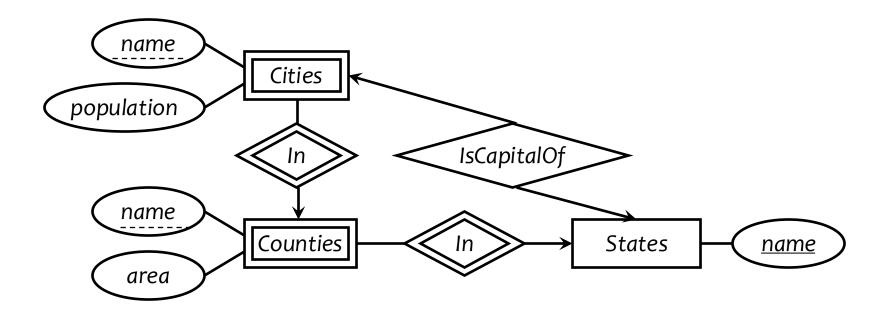

#### Assume the following:

- Names of states are unique
- Names of counties are only unique within a state
- Names of cities are only unique within a county
- A city is always located in a single county
- A county is always located in a single state

Keys, discriminator of entity sets?

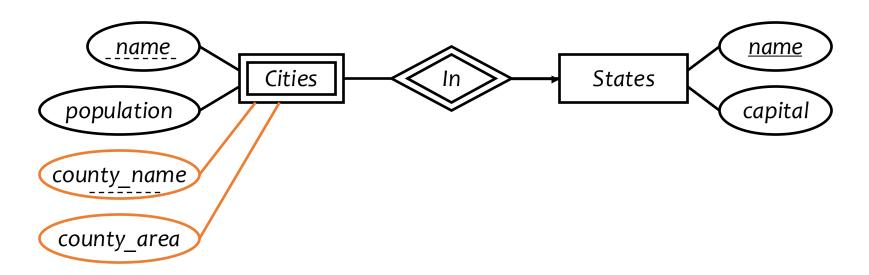

# Case study 1: final design

 Technically, nothing in this design prevents a city in state X from being the capital of another state Y, but oh well...

# Case study 1: why not good?

- County area information is repeated for every city in the county
  - Redundancy is bad (why?)
- State capital should really be a city
  - Should "reference" entities through explicit relationships

# Case study 2 (Exercise)

Design a database consistent with the following:

- A station has a unique name and an address, and is either an express station or a local station
- A train has a unique number and an engineer, and is either an express train or a local train
- A local train can stop at any station
- An express train only stops at express stations
- A train can stop at a station for any number of times during a day
- Train schedules are the same everyday

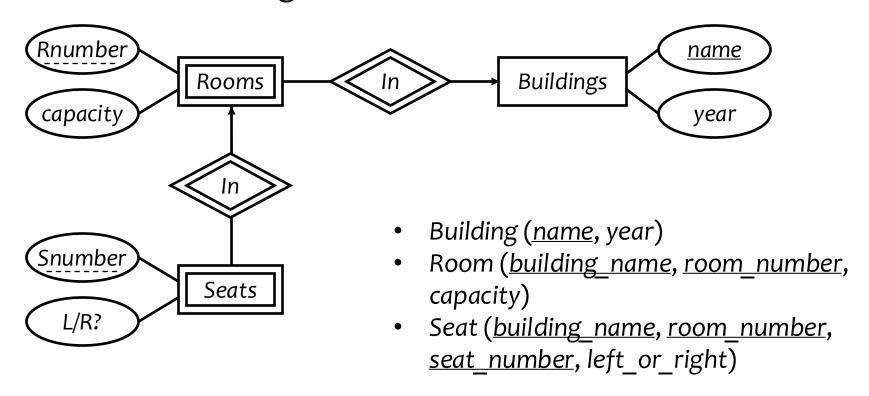

What are the entity sets, relationship sets, and their attributes? What are the types of relationships and cardinality constraints, keys, discriminators?

### What you have learned so far

Entity-Relationship (E/R) model

Next: Translating E/R to relational schema

### Case study 2: first design

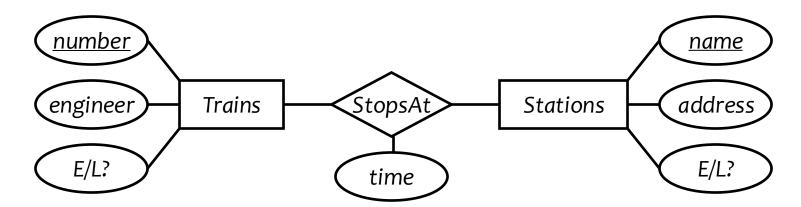

Design a database consistent with the following:

- A station has a unique name and an address, and is either an express station or a local station
- A train has a unique number and an engineer, and is either an express train or a local train
- A local train can stop at any station
- An express train only stops at express stations
- A train can stop at a station for any number of times during a day
- Train schedules are the same everyday

Why not good?

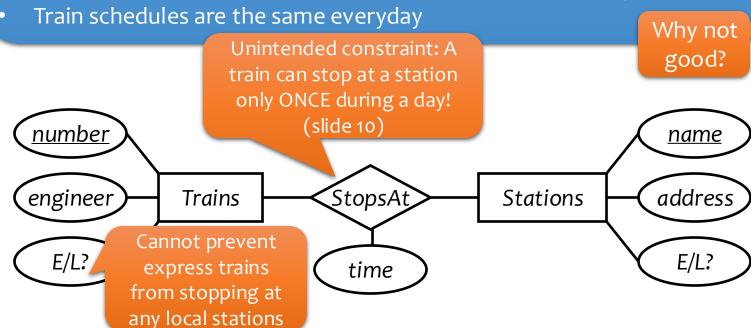

### Case study 2: first design

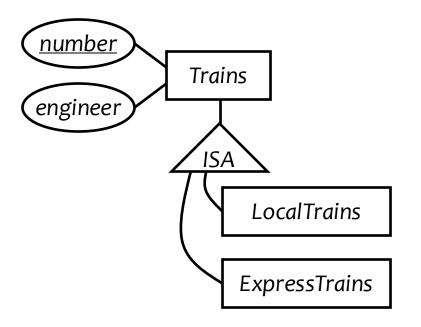

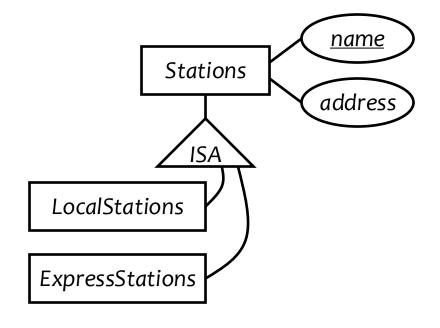

Design a database consistent with the following:

- A station has a unique name and an address, and is either an express station or a local station
- A train has a unique number and an engineer, and is either an express train or a local train
- A local train can stop at any station
- An express train only stops at express stations
- A train can stop at a station for any number of times during a day

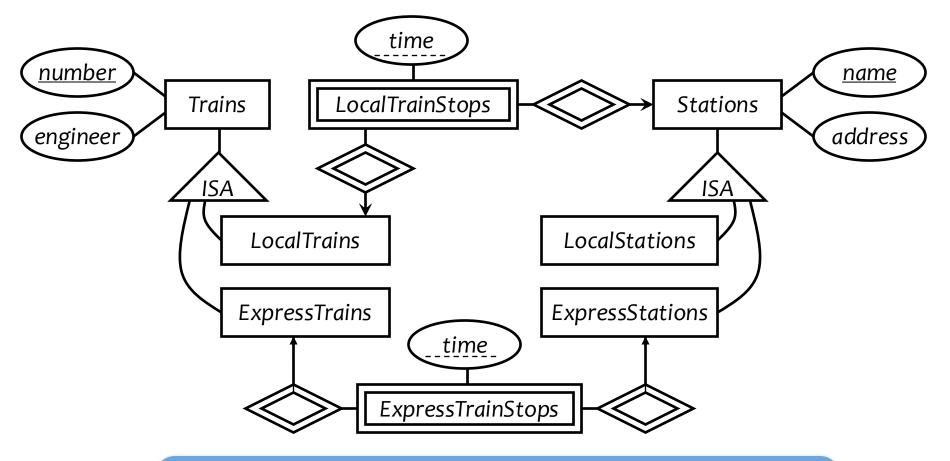

### Case study 2: second design

- A station has a unique name and an address, and is either an express station or a local station
- A train has a unique number and an engineer, and is either an express train or a local train
- .....

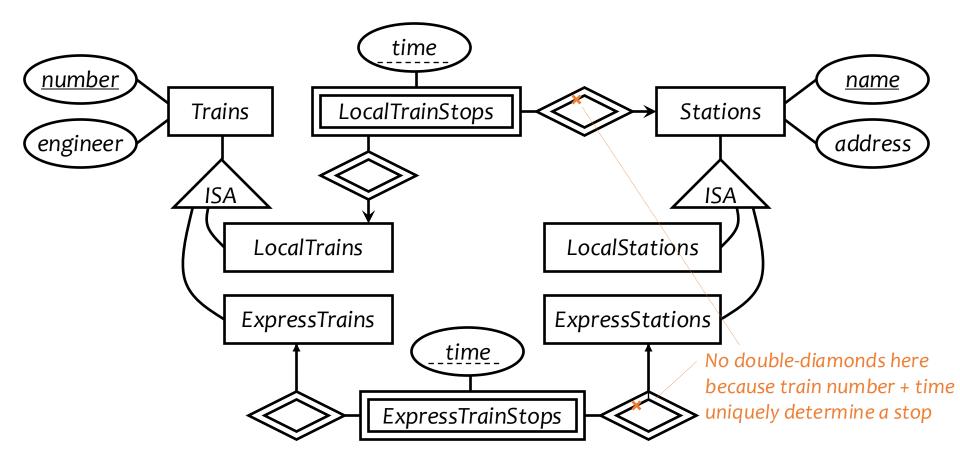

## Case study 2: second design

- •
- A local train can stop at any station
- An express train only stops at express stations
- A train can stop at a station for any number of times during a day

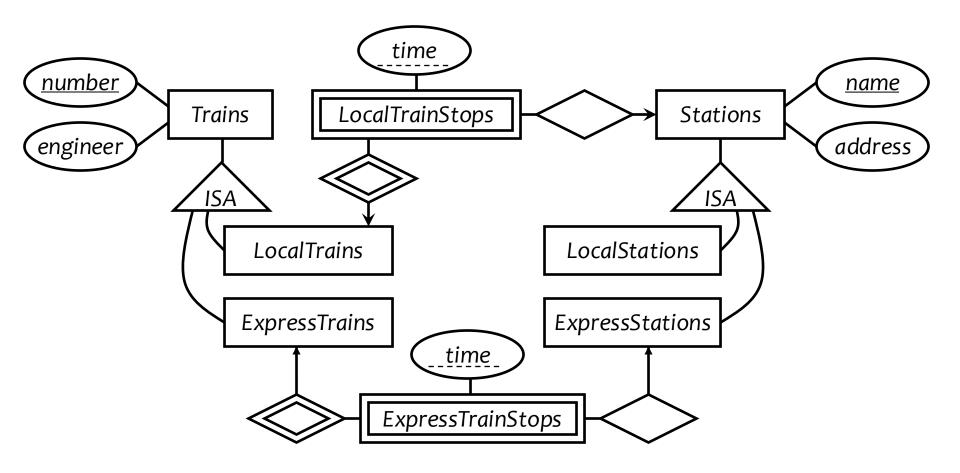

•••

### Case study 2: second design

Is the extra complexity worth it?
Yes! Captures more constraints and avoids unintended info

### Case study 2: final solution looks like..

## Case study 3 (Exercise)

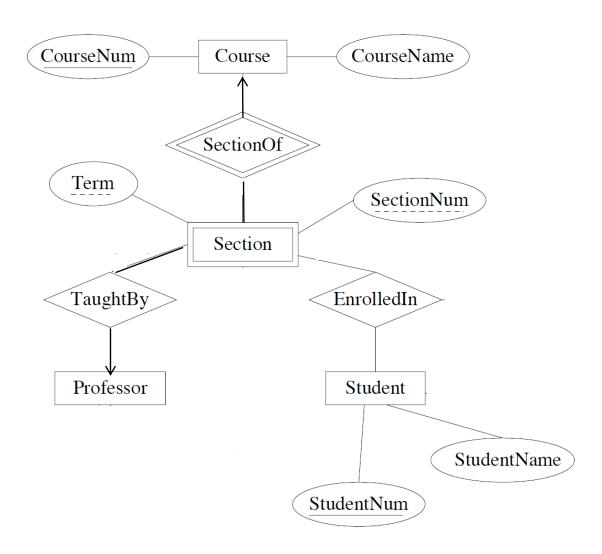

#### A Registrar's Database:

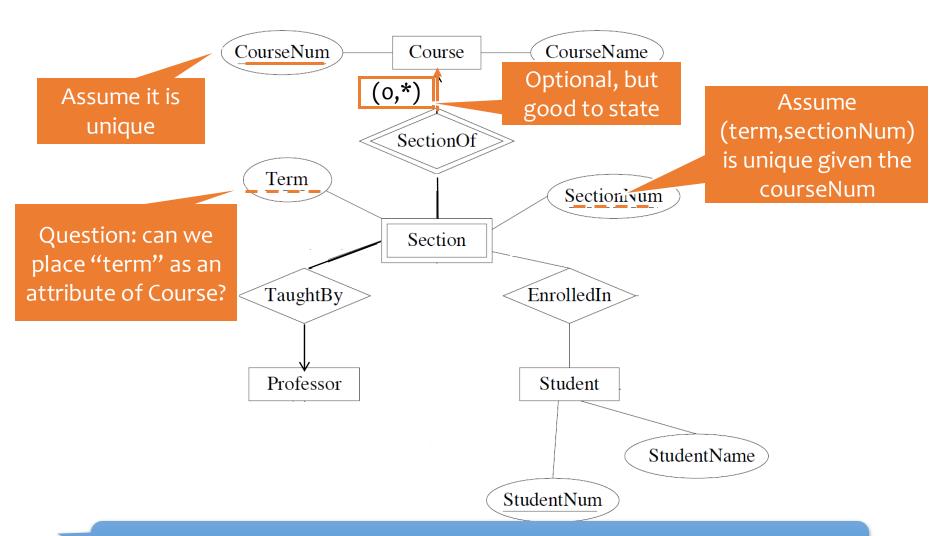

- Zero or more sections of a course are offered each term. Courses have names and numbers. In each term, the sections of each course are numbered starting with 1.
- Most course sections are taught on-site, but a few are taught at off-site locations.
- Students have student numbers and names.
- Each course section is taught by a professor. A professor may teach more than one section in a term, but if a professor teaches more than one section in a term, they are always sections of the same course. Some professors do not teach every term.
- Up to 50 students may be registered for a course section. Sections with 5 or fewer students are cancelled.
- A student receives a mark for each course in which they are enrolled. Each student has a cumulative grade point average (GPA) which is calculated from all course marks the student has received.

## Case study 3 (Exercise)

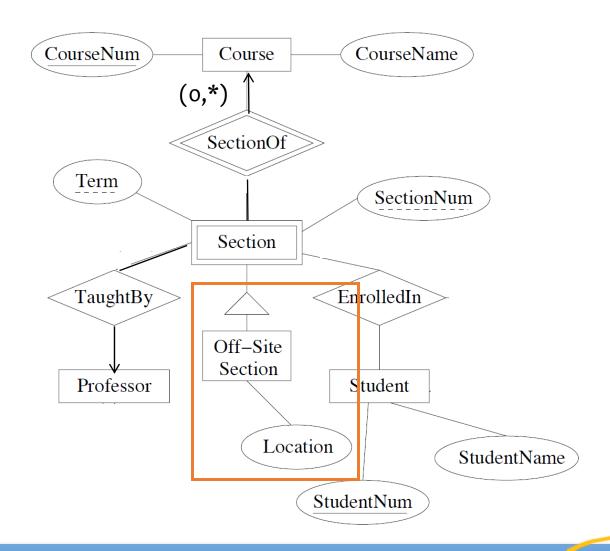

#### A Registrar's Database:

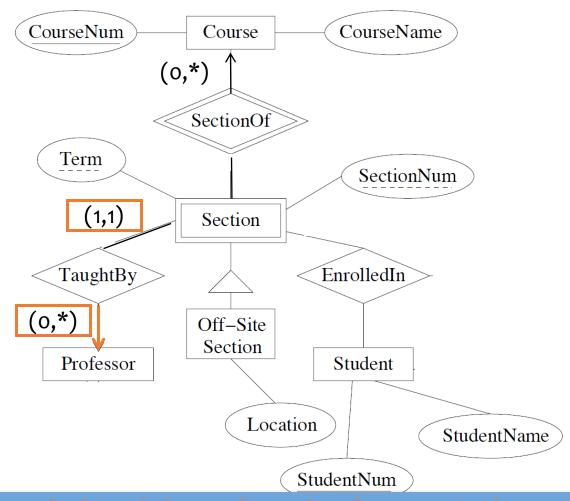

- Zero or more sections of a course are offered each term. Courses have names and numbers. In each term, the sections of each course are numbered starting with 1.
- Most course sections are taught on-site, but a few are taught at off-site locations.
- Students have student numbers and names.
- Each course section is taught by a professor. A professor may teach more than one section in a term, but if a professor teaches more than one section in a term, they are always sections of the same course. Some professors do not teach every term.
- Up to 50 students may be registered for a course section. Sections with 5 or fewer students are cancelled.
- A student receives a mark for each course in which they are enrolled. Each student has a cumulative grade point average (GPA) which is calculated from all course marks the student has received.

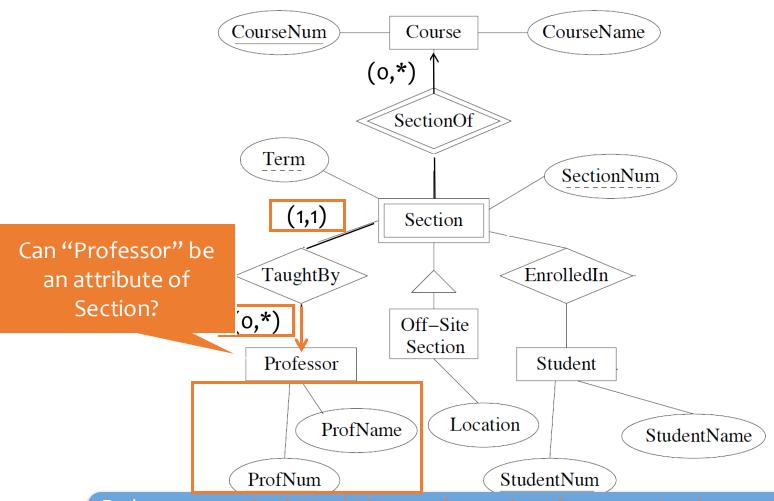

Zero or more sections of a course are offered each term. Courses have names and numbers. In each term, the sections of each course are numbered starting with 1.

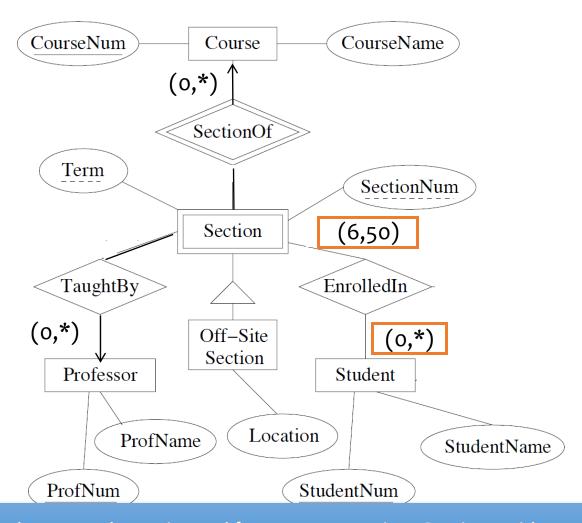

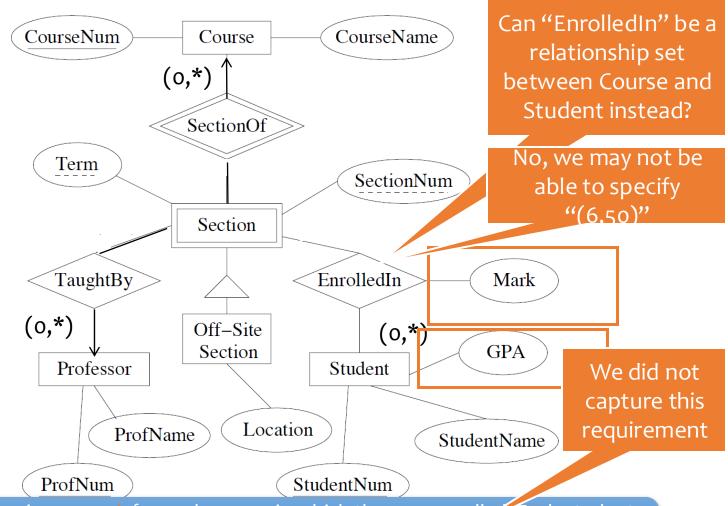

Each course section is taught by a professor. A professor may teach more than one section in a term, but if a professor teaches more than one section in a term, they are always sections of the same course. Some professors do not teach every term.

Each course section is taught by a professor. A professor may teach more than one section in a term, but if a professor teaches more than one section in a term, they are always sections of the same course. Some professors do not teach every term.

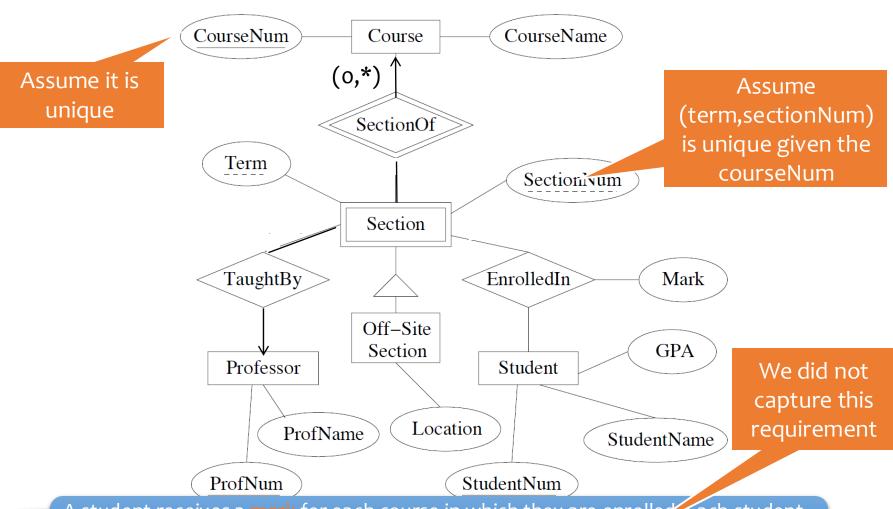

Up to 50 students may be registered for a course section. Sections with 5 or fewer students are cancelled. Students can enroll in 0 or more sections (implicitly derived).

A student receives a mark for each course in which they are enrolled. Each student has a cumulative grade point average (GPA) which is calculated from all course marks the student has received.

## Case study 3: possible solution

A student receives a mark for each course in which they are enrolled. Each student has a cumulative grade point average (GPA) which is calculated from all course marks the student has received.
