#### Introduction (cont.)

- What is Hadoop Distributed File System (HDFS)?
  - File system component of Hadoop
  - Store metadata on a dedicated server NameNode
  - Store application data on other servers DataNode
  - TCP-based protocols
  - Replication for reliability
  - Multiply data transfer bandwidth for durability

#### Architecture

- NameNode
- DataNodes
- HDFS Client
- Image Journal
- CheckpointNode
- BackupNode
- Upgrade, File System Snapshots

#### Architecture Overview

### NameNode - one per cluster

- Maintain The HDFS namespace, a hierarchy of files and directories represented by inodes
- Maintain the mapping of file blocks to DataNodes
  - Read: ask NameNode for the location
  - Write: ask NameNode to nominate DataNodes
- Image and Journal
- Checkpoint: native files store persistent record of images (no location)

#### **DataNodes**

- Two files to represent a block replica on DN
  - The data itself length flexible
  - Checksums and generation stamp
- Handshake when connect to the NameNode
  - Verify namespace ID and software version
  - New DN can get one namespace ID when join
- Register with NameNode
  - Storage ID is assigned and never changes
  - Storage ID is a unique internal identifier

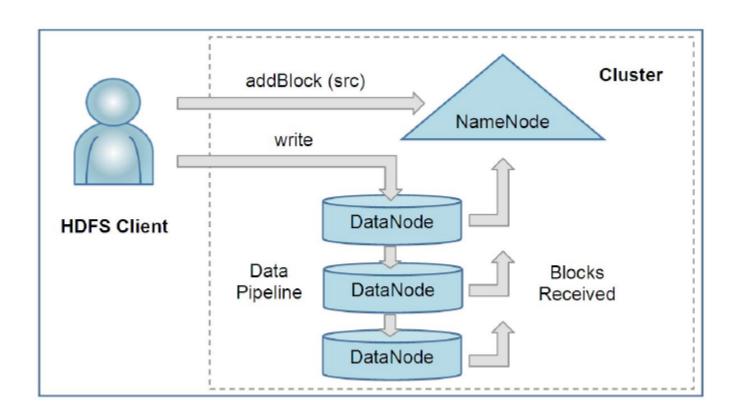

#### DataNodes (cont.) - control

- Block report: identify block replicas
  - Block ID, the generation stamp, and the length
  - Send first when register and then send per hour
- Heartbeats: message to indicate availability
  - Default interval is three seconds
  - DN is considered "dead" if not received in 10 mins
  - Contains Information for space allocation and load balancing
    - Storage capacity
    - Fraction of storage in use
    - Number of data transfers currently in progress
  - NN replies with instructions to the DN
  - Keep frequent. Scalability

#### **HDFS** Client

- A code library exports HDFS interface
- Read a file
  - Ask for a list of DN host replicas of the blocks
  - Contact a DN directly and request transfer
- Write a file
  - Ask NN to choose DNs to host replicas of the first block of the file
  - Organize a pipeline and send the data
  - Iteration
- Delete a file and create/delete directory
- Various APIs
  - Schedule tasks to where the data are located
  - Set replication factor (number of replicas)

### HDFS Client (cont.)

### Image and Journal

- Image: metadata describe organization
  - Persistent record is called checkpoint
  - Checkpoint is never changed, and can be replaced
- Journal: log for persistence changes
  - Flushed and synched before change is committed
- Store in multiple places to prevent missing
  - NN shut down if no place is available
- Bottleneck: threads wait for flush-and-sync
  - Solution: batch

## CheckpointNode

- CheckpointNode is NameNode
- Runs on different host
- Create new checkpoint
  - Download current checkpoint and journal
  - Merge
  - Create new and return to NameNode
  - NameNode truncate the tail of the journal
- Challenge: large journal makes restart slow
  - Solution: create a daily checkpoint

## BackupNode

- Recent feature
- Similar to CheckpointNode
- Maintain an in memory, up-to-date image
  - Create checkpoint without downloading
- Journal store
- Read-only NameNode
  - All metadata information except block locations
  - No modification

## Upgrades, File System and Snapshots

- Minimize damage to data during upgrade
- Only one can exist
- NameNode
  - Merge current checkpoint and journal in memory
  - Create new checkpoint and journal in a new place
  - Instruct DataNodes to create a local snapshot
- DataNode
  - Create a copy of storage directory
  - Hard link existing block files

## Upgrades, File System and Snapshots - Rollback

- NameNode recovers the checkpoint
- DataNode resotres directory and delete replicas after snapshot is created
- The layout version stored on both NN and DN
  - Identify the data representation formats
  - Prevent inconsistent format
- Snapshot creation is all-cluster effort
  - Prevent data loss

## File I/O Operations and Replica Management

- File Read and Write
- Block Placement and Replication management
- Other features

#### File Read and Write

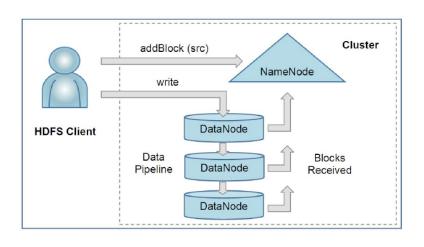

#### Checksum

- Read by the HDFS client to detect any corruption
- DataNode store checksum in a separate place
- Ship to client when perform HDFS read
- Clients verify checksum
- Choose the closet replica to read
- Read fail due to
  - Unavailable DataNode
  - A replica of the block is no longer hosted
  - Replica is corrupted
- Read while writing: ask for the latest length

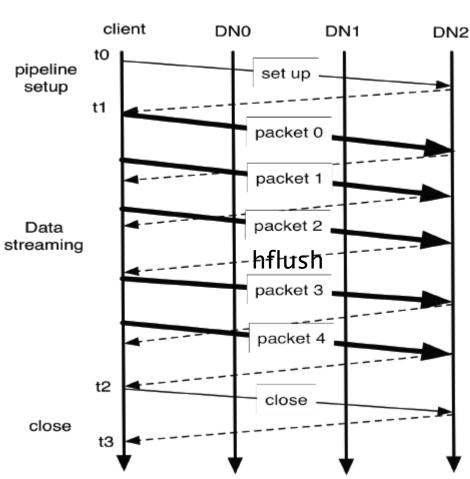

#### File Read and Write (cont.)

- New data can only be appended
- Single-writer, multiple-reader
- Lease
  - Who open a file for writing is granted a lease
  - Renewed by heartbeats and revoked when closed
  - Soft limit and hard limit
  - Many readers are allowed to read
- Optimized for sequential reads and writes
  - Can be improved
    - Scribe: provide real-time data streaming
    - · Hbase: provide random, real-time access to large tables

#### Add Block and The hflush

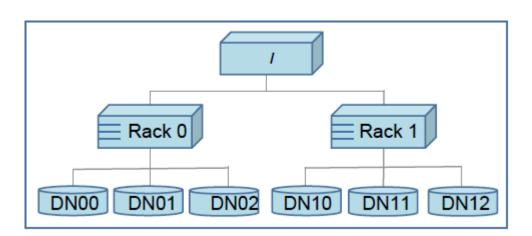

- Unique block ID
- Perform write operation
- new change is not guaranteed to be visible
- The *hflush*

## Block Replacement

- Not practical to connect all nodes
- Spread across multiple racks
  - Communication has to go through multiple switches
  - Inter-rack and intra-rack
  - Shorter distance, greater bandwidth
- NameNode decides the rack of a DataNode
  - Configure script

## Replica Replacement Policy

- Improve data reliability, availability and network bandwidth utilization
- Minimize write cost
- Reduce inter-rack and inter-node write
- Rule1: No Datanode contains more than one replica of any block
- Rule2: No rack contains more than two replicas of the same block, provided there are sufficient racks on the cluster

### Replication management

- Detected by NameNode
- Under-replicated
  - Priority queue (node with one replica has the highest)
  - Similar to replication replacement policy
- Over-replicated
  - Remove the old replica
  - Not reduce the number of racks

#### Other features

- Balancer
  - Balance disk space usage
  - Bandwidth consuming control
- Block Scanner
  - Verification of the replica
  - Corrupted replica is not deleted immediately
- Decommissioning
  - Include and exclude lists
  - Re-evaluate lists
  - Remove decommissioning DataNode only if all blocks on it are replicated
- Inter-Cluster Data Copy
  - DistCp MapReduce job

#### Practice At Yahoo!

- ▶ 3500 nodes and 9.8PB of storage available
- Durability of Data
  - Uncorrelated node failures
    - Chance of losing a block during one year: <.5%</li>
    - Chance of node fail each month: .8%
  - Correlated node failures
    - Failure of rack or switch
    - Loss of electrical power

- · 2 quad core Xeon processors @ 2.5ghz
- · Red Hat Enterprise Linux Server Release 5.1
- · Sun Java JDK 1.6.0 13-b03
- · 4 directly attached SATA drives (one terabyte each)
- · 16G RAM
- · 1-gigabit Ethernet
- Caring for the commons
  - Permissions modeled on UNIX
  - Total space available

#### Benchmarks

#### **DFSIO** benchmark

DFSIO Read: 66MB/s per node

DFISO Write: 40MB/s per node

#### **Production cluster**

Busy Cluster Read: 1.02MB/s per node

Busy Cluster Write: 1.09MB/s per node

#### Sort henchmark

| Bytes<br>(TB) | Nodes | Maps   | Reduces | Time     | HDFS I/0 Bytes/s  |                     |
|---------------|-------|--------|---------|----------|-------------------|---------------------|
|               |       |        |         |          | Aggregate<br>(GB) | Per<br>Node<br>(MB) |
| 1             | 1460  | 8000   | 2700    | 62 s     | 32                | 22.1                |
| 1000          | 3658  | 80 000 | 20 000  | 58 500 s | 34.2              | 9.35                |

#### Operation Benchmark

| Operation                | Throughput (ops/s) |  |  |
|--------------------------|--------------------|--|--|
| Open file for read       | 126 100            |  |  |
| Create file              | 5600               |  |  |
| Rename file              | 8300               |  |  |
| Delete file              | 20 700             |  |  |
| DataNode Heartbeat       | 300 000            |  |  |
| Blocks report (blocks/s) | 639 700            |  |  |

#### Future Work

- Automated failover solution
  - Zookeeper
- Scalability
  - Multiple namespaces to share physical storage
  - Advantage
    - Isolate namespaces
    - Improve overall availability
    - Generalizes the block storage abstraction
  - Drawback
    - Cost of management
  - Job-centric namespaces rather than cluster centric

#### Critiques and Discussion

#### Pros

- Architecture: NameNode, DataNode, and powerful features to provide kinds of operations, detect corrupted replica, balance disk space usage and provide consistency.
- HDFS is easy to use: users don't have to worry about different servers. It can be used
  as local file system to provide various operations
- Benchmarks are sufficient. They use real data with large number of nodes and storage to provide kinds of experiments.

#### Cons

- Fault—tolerance is not very sophisticated. All the recoveries introduced are based on the assumption that NameNode is alive. No proper solution currently in this paper handles the failure of NameNode
- Scalability, especially the handling of replying heartbeats with instructions. If there
  are too many messages come in, the performance of NameNode is not proper
  measured in this paper
- The test of correlated failure is not provided. We can't get any information of the performance of HDFS after correlated failure is encountered.

Thank you very much
